# THE EVANIIBAC. ENGIGN-ILIEN, AN AIRCIIIAC FAMIII OF IIMMENQIPEIEA. 

(Plates V-NV.)

## HY J. CHESTER BRADLEY.

When in the fall' of 1901 I publisher in the 'lransactoons of the American Entomological Society a paper on the Aulacine of N. rth America,* I intended it as the first one of a series of three papers, which I expected shortly to complete, one on each subfamily of the Evaniidse. Through many intervening circumstances this sign has been frustrated, but out of it has grown the present aper.
This enntribution deals primarily with the Evanimæ, and contains as complete a monograph of the North American species of that subfamily as I have been able to prepare. But I have found a sudy of exotic genera and species necessary to a satisfactory concept of the classification and relations of the group. Indeed, the variations of form shown by the members of this group and their comparison with each other and with other groups, native and exotic, has been to me the most interesting part of the work, and I trust that I may be pardoned if I have laid more stress on it than is customary in purely systematic works, where often little attention is paid to characters not found desirahle for use in keys.

As a second part of this paper I have embodied the result of my study of exotic forms. Here are included descriptions and remark: on the genera and species of the world, a table to the genera, and finally a table to all the described species whose generic position I could with reasonable certainty identify. The latter have been compiled almost entirely from literature, which is I believe the only practicable method, because no one person can expect to accumulate even a large proportion of the species of the work. 'These certainly must prove unsatisfactory, and must contain many errors, for the descriptions are often very incomplete, and it is difficult to compare those drawn up by difierent authors. But I hope that

[^0]they will be of some real service to students desirous of identifying exotic species, and who at present must perforce wade through a great mass of more or less unsatisfactory descriptions in several languages and innumerable publications. In preparing them I have userl my best judgment in selecting characters that would be reliable and eary to use, but have of course been greatly hampered in this respect by the limitations of the deseriptions. In such cases as I have heen able to eximine the species in question, matters have of course been much expedited.

I shall hegin the paper with a short consideration of the family as a whole; then of the Aulacins, tabulating the genera of the world and in part supplementing, in part revising, my former paper on the North American species. Then I shall take up the Foenine, treating it briefly. I regret that at present I see no prospect of being able to prepare a more complete monograph of our North American species of this subfamily. In perhaps no group that I have studied have the characters beeu so variable and difficult of tabulation, so that it would require a very considerable amount of time and study. Then will follow the parts on the Evaniine as above described, and I shall conclude with a catalogne of the species of Evaniine of the entire world, distributed according to their proper genera.

I wish to express my obligations to Professor Comstock of Cornell University, who has placed at my disposal in the entomological laboratory of that institution, where most of this work has been carried on, every facility for study that could be desired, and has kindly reat the manuscript: to Dr. A. D. MacGillivray, also of Cormell University, for constant assistance, suggestions amd courte sies of many kinds, and also for reading the manuseript: to the authorities of the United States National Museum for the loan of the very valuable collection of Evanidae belonging to that Musemm: to the American Entomological Society for the loan of many specimens; to Mr. C. T. Brues and Dr. I'. I'. Calvert for the presentation of several specimens: to Mr. Henry $L$. Viereck for the presentation of numerons valuahle specimens, partieulally of North American Hyptia, and some undescribed species from British Guianat to Mr. G. V. Itudson of Wehington, New Zealand for the presentation of $t w o$ species of Fonine including the type of the grenus I'seudofatus: to Prolessor Merbert Oshorm, Professor E. D.

Sanderson, Mr. Wm. Beutemmüller, Professor Carl F. Baker, Dr. A. D. Hopkins, Mr. Erich Daecke and others for the loan of numerous specimens: to Mr. C. S. Spooner and Mr. H. J. Hammond for assistance with the manuseript.

The figures of wings on Ilate: XI-XV inclusive were made as follows: the wings were removel from the right hand side of the insect, monnted on slides and then photographed. Blue-prints were made on drawing paper conted with blue-print solution. The ontlines of the veins were then drawn on the print with water-proof India ink, and after thorongh drying the print was bleached in a strong solution of potassimm oxalate, leaving the ink drawing on a white background. Thus almost mechanical accuracy was obtained in the representation of the thickness and position of the veins. Figs. 67,82 and 87 were copied by a similar method from published figures, inasmuch as no specimens of these genera were twailable. Figures 18, 19, 62, 63 and 64 were drawn free hand. The remaining drawings were made with a camera lucida. The drawings on Plates VII and VIII were all made to the same seale, as were those on Plate IX. The claws on Plate IX were monnted on slides, hence present a somewhat different appearance from what woukl be seen in situ. Plate $V$ is from direct photomicrographs.

I have been able to sturly specimens of all the described genera except the following: Evoniscus Szepligeti, Ecomiellus Enderlein, Aulucinus Westworl, semenomia Kieffer and Aulucus Jurine; also of all the North American species of Aulacine and Evanimat except Hyptin breviculcor Kieffer, Aulucus eryphroguster Kieffer, Pristunlacus faripes Kieffer.

The Evaniidat are an anomalous family of parasitic Ifymenoptera, probably of very amcient stock, and as is often true in such cases, although well represented in number of species, the individmals are almost invariably to be counted as rare insects, and are not usually well represented in collections. Because of their amomaly they have formed, as I have before remarked, a dumping around for very many peculiar forms whose relationships have puzzled investigators. In this way the following genera and perhap others have at one time or another been inchoded in the family, in addition to those we at present inchude: Prlecinus, Stephumus, Mugiselus, I'uxillomue, Trigonulys, Monomuchus, ()phionellus, Megalyow, C'(q)itomius, Comorrelius. Leptoformue, etc. 'To-day most anthors are
agreed in restricting the family to the scope recognized in this paper, except that some include with it the Stephanidæ. While I think the latter are sufficiently distinct to form a fanily by themselves, I believe they really are closely related to the Evaniidæ, particularly through the Foenine. There is a similarity in wing venation, and the insertion of the abolomen in Stephanus is on the lower part of the propodeum, but above the coxa. Even the babitus is somewhat similar. It is not improbable that the Foninz may really be more closely related to Stephanidæ than to Evaniinse or Aulacine, and should really form a subfamily of the former rather than of the Evaniidre. Although really I think all of the subfamilies here recognized are entitled to family rank.

There are two characters that are usually employed in distinguishing the Evaniidæ. These are the presence of the cell C in the front wings (Fig. 69), and the insertion of the abdomen on the propodeum far ahove the posterior cosæ. Neither are absolute, and may be used ouly in conjuction with other characters. The Stephanidr, as before mentioned, have a distinct costal cell, while several genera of Braconide have the abdomen inserted on the propodemm far above the coxa; some of the Stephandae less distinctly so. The Ropronide have a distinct costal cell, but the abdomen inserted normally.

In designating the wing veins I have employed the system proposed hy Comstock and Needham.* I do this because I believe that the venation thereby takes on an intelligible significance. The veins are, I am convinced in the main, correctly homologized with those of other orders. I intend to employ this system as far as possible in my future studies of the Hymenoptera. I refer the reader who is not familiar with it to the paper of Comstock and Needham just cited, and for its application to the Hymenoptera, particularly to a paper by Dr. A. D). MacGillivray $\dagger$ on the wing venation of the Tenthredinoidea, where the subject is treated very clearly in Sections II and IIJ, pp. 574 to 583 . An appreciative and careful study of these sections and their accompanying figures will I am sure make the matter clear to any onc.

[^1]For convenience I give below the terms ased by Cresson in his Synopsis of the North American Hymenoptera and their corresponding desiguation in this paper (Figs. 67 and 69).

## veins.

Coita $=C$.
Subcosta $=\mathrm{Sc}+\mathrm{R}+\mathrm{M}$.
Marginal or radial vein $=r, \mathrm{R}_{\mathrm{r}}, \mathrm{R}_{3+4}$ and $\mathrm{R}_{3}$.
1st transerse cuhbitus $=r-m$ and $\mathrm{R}_{\mathrm{s}}$.
$2 d$ transverse cubitus $=\mathrm{R}_{5}$.
3d transverse cubitus $=\mathrm{R}_{4}$.
Ba*al vein $=$ Mand m -cu.
Cubitus $=M, M_{1+2}, R_{5}+M_{1}$ and $\mathrm{R}_{4-5}+\mathrm{M}_{1}$.
1st recurrent vein $=\mathrm{M}_{3+4}$.
2. 1 recurrent vein $=\mathrm{M}_{2}$.

Discoidal vein $=\mathrm{MI}_{3}$ and $\mathrm{M}_{\text {i }}$.
Subdiscoidal vein $=\mathrm{m}$ and $\mathrm{M}_{2}$.
Externo-medial vein $=\mathrm{Cu}$ and $\mathrm{Cu}_{2}$.
Transverso-medial vein $=\mathrm{MH}_{4}+\mathrm{CH}_{1}$.
Anal vein $=1 s t+2 d+3 d A, \mathrm{Cu}_{2}+1 \mathrm{st}+2 \mathrm{~d}+3 \mathrm{dA}, \mathrm{M}_{1}+$

> CELLS.

Costal $=\mathrm{C}$.
Stigma $=\mathrm{Sc}_{2}$.
Marginal or radial $=21 \mathrm{R}_{1}+\mathrm{R}_{2}$.
1st submarginal or cubital $=\mathrm{R}+1$ :thin.
$2 d \quad$ " " " $=\mathrm{R}_{5}$.
3 d " " " $=\mathrm{R}_{4}$.
4th " " " $=\mathrm{R}_{3}$.
Median or externo-medial $=\mathbf{M}$.
1st discoidal $=\mathrm{M}_{1}$.
$2 d \quad " \quad=M_{3}$.
3 d " $=1 \mathrm{st} \mathrm{M}_{2}$.
1 st apical $=2 \mathrm{JlH}_{2}$.
2 d " $=\mathrm{M}_{\mathrm{l}}$.
Submedian or externo-medial $=\mathrm{Cu}+\mathrm{C}^{\prime} \mathrm{m}_{\mathrm{I}}$
Anal $=3 \mathrm{dA}$.

The combination of veins and consequent nomenclature will generally be different for each abscissa. In Fig. 73 it will be seen that the medial cross-vein and the second branch of media form apparently a single vein with no indication where they join. In such cases where two different abscissas are joined end to end without indication of the place of mion, I have designated the entire vein thus formed by the name of each abscissa connected by "and", or if three or more are thus joined, use a comma between the first two and "and" between the second, as m and $\mathrm{M}_{2}$, or, again, $R_{s,}, R_{3+4}$ and $R_{3}$. The + mark of course is only used where two or more veins unite side by side, as $\mathrm{R}_{4-5}+\mathrm{M}_{1+2}$.

On Plates XI-XV inclusive are arranged figures of all the types of wings known to occur in the family, in what I believe to he an order ascending from the most generalized to the most modified, especially within each subfamily. The Aulacina are very evidentiy the most generalized. Take for example Aulucinus (Fig. 67), $R_{4}$, $\mathrm{R}_{5}$ and all of $\mathrm{M}_{2}$ are present. Omitting for the present the Fominæ (Figs. 72-74), we find in the wing of Evania (Fig. 76) only a slight modification. $\mathrm{R}_{5}$ is lost and also the transverse part of $\mathrm{M}_{2}$. M has migrated far forwards along the radius, carrying with it m-cu. In this subfamily modification then proceeds by atrophy, until in Evaniellus (Fig. 87) only C and Se are left. The Fomine (Figs. 72-74) we may look upon as a side line. We camot compare the degree of their specialization with the others, hecause it has been in an entirely different direction. It seems reasonable to suppose that they may have arisen as an offisont of Aulacine (compare Figs. 71 anl 72), or they may have arisen from somewhere among the ancestors of the Stephanide. At any rate in wing venation and other characteristics they are highly modified. Of course I do not base my conclusions as to the relations of these gromps solely on the wings, but these are easy of illustration and description, and in all more reliable for comparison than any other single chatacter, hence I emphasize them here.

L'Abbe Kieffer* criticizes the table to the subfamilies of Evaniidie that I published in my former paper, on the grommts that the characters given do not apply in all cases. But I think that his eriticism is unfar, since the table was intended only for the North American forms, for whichsofar as am atwe it holde good. All

[^2]the exceptions urged are for exotic species. His own table published in the same place is open to the same objections. Thus undel his tribe Evanime he says: "Nervare basale aboutisant an stigma, rarement évamonie dans sa partie superienre." In the genera Hyptiu, Semoromyia, Semuroloyaster, Evuniellus and sometimes Konscoume, the "nervare basale" is wanting. Agatu he says: "Abdomen . . . . ellipsoidal chez le mile." In Hypticu and others the abdomen in the male is romd and indistinguishable from that of the female in shape. I think that the chatacters employed in the following table will be found constant, except that I am not certain whether the folding of the wings is constant in all Fieninæ or unt. It is in all cases that have come under my observation.

## TABIE OF THE SUBFAMILIES OF EVANIIDE.

1. Front wings with the transverse part of Ma present (Fig. 67) ; not folded longitudinally; hind wings without a posterior lobe (Fig. 69) ; metasternum not prolonged into a furcnla; abdomen clavate, the basal segment not filiform-petiolate, nor strongls contrasted to the second in form . ..... ...................................................... AULACIN E.
Front wings with the transverse part of $\mathrm{M}_{2}$ absent (Figs. 72 and 76) ...... (2).
2. Hind wings without a posterior lobe (Fig. 72) ; front wings folded longitudinally as in Vespoidea; metasternum not prolonged into a furcula; abdomen clavate and compresserl, the basal segment not filiform-petiolate, nor strongly contrasted to the second in form........FCNINE.
Hind wings with an almost separated posterior lobe (Fig. 76) ; front wings not folded longitudinally ; metasternum prolonged into a furenla belween the posterior coxa; abdomen with the hasal segment filiform-petiolate, strongly contrasted to the following segments in form, the batter togetler compressed, oval ( § ), triangular ( $\mathcal{Q}$ ), or nearly round in botb sexes........................................................ EVANHN.E.

## F(FNIN.

Following Schletterer, authors have of recent years used crasteruption as the mame of the typical genus of this family. But Cocsteruption of Latreille (1797) is a nomen nudum-no species being mentioned. In 1798 Fabricius deseribes Fonns with juculator and usisectutor as speries. Latreille in $1 \times 02$, Hist nat. Crust. and Insec., iii, 329, says: "J'avois établi ce genre avant loabricins, sons le nom de Gustoruption; mais, comme ce dernier mot est trol dur, i' adopte avec plaisir la denomination de ce matumaliste."

As before remarked, the Franinte show mmistakable relations to the Stephanida.

The wing of Myptioyuster is the most gencratized in the sub-
family．In Frenus（Fig．73）the base of the longitudinal part of M has become interstitial with $\mathrm{Cu}_{1}$ ，crowding m－cu out of existence and greatly reducing the size of the cells $\mathrm{M}_{3}$ and $\mathrm{M}_{4}$ ．In Psendo． femus（Fig．74）the condition is the same，except for an arlditional step，the vein $\mathbf{M}_{4}$ being lost and cells $\mathbf{M}_{3}$ and $\mathrm{M}_{4}$ thas thrown together．

The habitus is similar in all the species that I have studied，the proportions being always slender，the neck long，and the posterior tibie very strongly clavate．But not in the genus Hyptioguster，at least not in $H$ ．humeralis，in which the form is stouter，the neck short and the posterior legs stout ；the femora very stout，as though for leaping；the tibie stout but not clavate；the tarsi very short， exclusive of the claw，less than one－thitd as long as the tibire，the second and third joints being extremely short，much broader than long，while the claw is quite large．The month parts are much enlarged and used for sucking（Figs，20－21）．

The claw（Fig．43）is always simple；the mouth parts are shown in Figs．20－23．

An interesting character is found in the longitudinal folding of the wings，as in the Vespoidea．Outside of these there is only one other genus of Hymenoptera known to have this habit，namely Leucospis，a Chalcid．

A quite extensive account of the life history of Fomus（Gustermp－ tion）is given by Hoppner．＊The genus is parasitic on the larve of aculeate Hymenoptera，and has been bred from Prosopis，Trypory－ Ion，Osmiu，Eriades，Odynerus，Colletes and Cemones．In the col－ lection of Cornell University is a specimen lacking an abdomen，but probably $F$ ．incertus，bred from the nest of P＇assulocus distinctus Fox．

Only Fienus occurs in the United States．

## TABLE TO THE GENERA OF FEENINE．

1．In the front wings m－cu absent（Figs．73，74），the hase of the longitudinal part of M joining $\mathrm{Cu}_{1}$ ；［1＇osterior tibise swollen and clavate；habitus slem－ der，the neek and head nsnally long］$\dagger$ ．．．．．．．．．．．．．．．．．．．．．．．．．．．．．．．．．．．．． 2 ）．
In the front wings m－en present，the base of the longitudinal part of J being removed from（ $1_{1}$（Fig．72）；［Posterior femora and tibix sometimes much swollen but mot clavate；the tarsi sometimes very short；joints $\approx \mathrm{f}$ broader than long；habitus stouter，head and neek not elongate．］＊＊

Hybliogatmer Kieffer．
（Type Gusteruption antomule Sohletterer）．
Allg．Zeitsclur．f．Entom．，ix，p．97，1！114．
i The bracketed characters may not always hold true，but do in all the species that I have seen．
$\therefore$. The free part of $\mathrm{I}_{ \pm}$presput (Fig. 73 ) . F'uenus Fabricins (finsteription anct ('Trpe Ichnenmom asvectator L.

(True (iasternption peduculutum schietterer.)
Fenus maculicornis Cameron, from Mexico, belonge to the genuPsentojoraus.

TABLE TO THE NORTH AMERJCAS SPECIES GROUPS OF FOENUS. AND THE SJECIES OF THE MONTANUK GROUI'.

1. Ovipositor of the females as long as the abdomen ..........tarsatorius group. Ovipositor of the females about one-quarter as tone as the abdomen.
mortanus yroup ( $\sim$.
2. Medial mesothoracie lobe shagreened, not striate . . . . . . . . . . . . . . . . . . . . . . . 3 . Medial mesothoracie lobe transversely rugose-striate.......miceurat Kicffer.
3. Secoud, third and fourth abdominal segments banded black and red.
nIontinns incerfus Cresson.
Apex of second, third, fourth and fith abdominal segments except dorsal spots, entirely red, middie amd posterior legs of en red beweath.
nimbitinus ('resson.

## Fresums mositanis Cresson.

1864. Fomus montunus ('resson, l'roc. Ent. Suc. Phila. iii, p. 102 ).
1865. Fœnus incertus Cresson, ibid.. 1). 13:3 (= race incertns).

1866. Gnsteruption nevedense Kietfer. Invert. pacifica, i, p. 11 (race montum,s.

Black, ahdomen often partiy rufous, legs sometimes light. oripositor $\gtrsim . \overline{\mathrm{j}}-\boldsymbol{3}$ m mon Length $7.5-13 \mathrm{~mm}$.
8.--Ilead black; oeciput and face very minuteis roughened, with close punctures several times smaller than the facets of the eye, giviug the whole a dull opacque lustre: jaws black. punctures larger and not so close; no area on the face separated by grooves; face impubescent. except for a fringe of yellow hairs on the edge of the clypeus, which is emarginate, its artienlation marked by a vers fine suture : a short ridge between the antenne above; face not narrowed : head very broadls rombed behind the eves, posterior margin simple; first joint of flageilum strongly clavate, two-thirds the size of seeond, which is subcrlindrical, third searcely longer than the second, but perfectly erlindrical; antemae more minutely punctured than the face, glabrous to the middle of the third segment of the flagellum, where it becomes jubencent; head beneath glabrous. Neck short, finely wrinkled anteriorly below, smooth posterioris, with a few soattered punctations: above more coarsely reticulate. Thorax black: margin of prothorax wavs, withont any well-market tooth ; propleura and mesothoracie lobe finely roughened with punctures somewhat larger than the facets of the ere. especialls the former; parapsides smonth and more sparingly punctulate, without an impressed longitudinal line; meso-and metapleure more coarsely punetuhate; scotelnm rers thely punctulate; wings hyaline, without violareous reflection, reins dark. Legs neariy black, somewhat subcastaneous. pernly and most minntely punctulate, tibiæ and tarsi covered with short pubeseence. Abdo-
men black, second and third segments tipped with rufous; a rufous spot on each side of the third segment and ventrally; abdomen much compressed, smooth and with a dull, not silky lustre.
\}.-Similar to female, but slightly more pubescent and punctations generally a little larger.

The description applies to the race incertus.
The races montamus and incertus merge one into the other. Vontanus has much more red on the abdomen, violaceons wings, and very frequently the under side of the middle and posterior legs red. It seems to be more common in Nevada, and to extend eastward into Colorado (West Cliff), and northward into Oregon (Mt. Hood) and Washington. Incertus is the common form in Colorado (type locality) and is also recorded from New Mexico (Beulah, August 17th, Dr. Skinner; July 11th, T. D. A. Cockerell), from Oregon (Mt. Hood), and from Washington. Further east it occurs in Canada; New Hampshire; Massachusetts; Pemnsylvania (Castle Rock, Dr. Skinner), and Virginia.

The eastern specimens seem to differ slightly from the western ; they usually have a white base to their posterior tibia, while in westeru individuals the tibise are usually entirely black.

## Fonus micrura Kjeffer.

1903. Gusteruption micrura Kieffer, Ark. f. Zool. i, p. 556.
S. -10 mm . Black. Head opaque, very finely shagreened; eyes short, hairy ; occiput nearly semicirenlar, slightly less than half the length of the eye; posterior margiu simple, weakly concaved ; posterior ocelli somewhat more widely separated from each other than from the compond eyes; cheeks very short, shorter than the second antemal segment; antenne dark brown, paler at the apex; the second segment longer than thick, two-thirds as long as the third; the fourth a little longer than the third.
Thoras dark red ; neck and upper side of the thorax almost black ; nerk short; pronotum with an indistinct tooth on the anterior angles; medial mesothoracic lobe thickly, rather finely transversely rugose-strjate, the lateral and posterior parts of the mesonotum leather-like, as also the scutellom, and the propleure and mesoplenra; propodeum reticulate. Wings hyaline; posterior wings with three costal hooks, without cells; coxe and legs brownish yellow; posterior legs darker, the hase of their tibice white ; posterior coxe transverse-striate ; metatarsus as long as the four following segments united. Apical third of the second, third and fourth abdomimal segments yellowish-red ; owipositor scarcely longer than the petiole; vagina entirely black, their apex weakly spindle-shaped.

Male similar to the female.
The description is tramslated from Kieffer.
The color of the thorax is usually entirely back.
Type locality, Illinois. I have seen specimens from New Hampshire (New Crlenn House, White Mtns.) ; Massachusetts and Virginial.

## Foenns tarsatorins say.

(*) 155l. Fcens barnstomi Wैestwood, ? Trans. Ent. Soc. London, n. s., i, p. 220.
1559. Fcemus fersutorius Say, ? Entom. North Amer. i. p. 215.
1809. Gusteruption tursutorizm shlett, Ann. d. k. k. Nath. Hofm. Wien, ir, p. 4 s.
1903. Gusteruption intricutum Kieffer, Ark. f. Zool.. i, p. 556.

Black or brown; punctures on dorsum deep, large and seattered among the coarse wrinkles. Length $10-14 \mathrm{~mm}$. Ovipositor $10.5-13 \mathrm{~mm}$.

ㅇ.-Head black, vers minutely punctulate, somewhat shiny on top, slightly silverr-sericeous between the eyes and antema, mandibles testaceons, tipped with rufons; margin of clypeus sinuate, emarginate in centre; head bebind eyes narrowed, margin mot reflexed; antemse pubescent toward apex, from abont the third segment of Hagellum; this short clavate. Thorax black, laterally silvers sericeous; dorsum coarsels reticulate or transrerse-wrinkled, whth large punctures between and small ones on the wrinkles or meshes; propodeum coarsels reticulate. Wings hrialine, irridescent, withaut violaceous reflection; veins pale. Four anterior legs entirely testaceons, jucluding coxie; posterior coxa hlack, finely transverse-wrinkled; femora reddish-brown; tibiæ white at hase. eapecially anteriorls, club brown; tarsi white, apex brown. Abdomen silks. black, two or three segments tipped with a ferruginous lateral spot. Borer red, sheaths black, tipued with white.

If this proves to be identical with barnstomi of Westwood, that name will replace tarsatorius say.

Hab.-Massachusetts (Medford, G. Dimmock); North Carolina; Virginia; Canada; New York (Ithaca); Pemnsyvania.

Foenus firagilis nor. spec.
Very frail and slender, abdomen brown to black, with ferruginous spots, legs dark brown, wrinkles on the dorsum subohsolete medially, d windling into punctures. Length 11 mm . Ovipositor 913 mm .

ㅇ.- Head black; face clotbed laterally and on the border of the clrpeus wibl silvery sericeous pubescence: face sparingly, vertex more closely covered with punctures the size of the facets of the eres; the maudibles are rufous. the apieal thoth small. blunt, and the apex, which is also somerrhat hlunt, is not prolonged beyond it, very slightly punctured; elypeus sinuate laterally, very broadly emarginate medially; its articulation with the face and an area beneath the antenne well defined; occiput with a tendency toward finc l ransvere wrinkles, cheeks narrowed behind the eres, posterior edge acute; first joint of the flagellum short, clavate, together with the second longer than the third by ahout half the length of the first. Neck long, broad at hase and tapering strongls at the apex; strongls sculptured with transverse wrinkles, irregular, and dather widely separated. Prothorax similarly sculptured; on the lobe of the mesothorax the sculpture is similar hut more regular towat the sides and the rear, in the middle anteriory the wrinkles become subohsolete, dwindling into mere punctures: propodeum eoarsely reticulate; sides of thomax silvery sericeous; prothoras wilh a well-marked acute tooth on the anterior margin. Wings hyaline irridrseent. without the heautiful violaceous reflection found in some of the other species.
veins and stigma dark. Legs entirely dark brown, except a white ring near the hase of the posterior tarsi, and a subwhite ring at the base of the posterior tibie. broad in frout and ohsolete bebind ; posterior coxa very finely transverse mghluse. Abdomen silky, brown at base, grading to blaek at apex, varied with two ferruginous spots on each side near the middle. Borer red, sheaths black, pale at apex.
§.-Similar, except that the apex of the mandibles is a little longer, the clypeus a little more deeply emarginate, and the second joiut of the flagellum short.

Five specimens with no rariation, except that the ferruginous spots on the abdomen sometimes extend toward the base. The stature is very frail.

Mab.-Montana, Nevada, Oregon (Mt. Hood).
Type.-In the American Entomological Society's collection.
Fomis pattersonte Melander and Brues.
1902. Gasteruption puttersonæ Mehander and Brues, Biol. Bull., iii, p. 35.
1904. Gaster"ption pyrrhostermum Kieffer, Invert. pacific, i, p. 41.

Black, legs red, abdomen ferrugino-maculate. Thorax sub-coarsely reticulate. posterior coxe more finely reticulate. Length 12.5 mm .
§.-Head black; face slightly silvery pubescent; mandibles rufous, tipped darker, shining and impusctate toward the acnte apex, slightly punctured at the base; clypens sinuate, broadly emarginate, without tooth in centre; face vers sparingly covered with punetures much smaller than the ocelli; ponctations on the occiput larger and rumning into close fine transerse wrinkles; antemad pubescent, with the second segment of the flagellum short; occiput and head beneath covered with fine rellowish pile; head behind the eves very brief, subtruncate, margin not reflexed. Neck short, it and the entire thorax are covered with eoarse and more or less regular reticulations, not confluent on the mesothorax, and about one-half the size of the ocelli. Thorax entirely black, its sides and the neck silvery sericeons, prothorax with an aeute tooth on the lateral anterior angles. Wings subhyaline, without violaceous reflection and but slight irridescence; nervures and stigma dark. Fonr anterior legs including coxa rufotestaceons; posterior deep rufous, tending to castaneous, the base of the tibixe with a white ring; posterior cosat rafons, much more finely reticulated than the thorax. Abdomen sub-silky, black, with ferruginous lateral spots on the first two or three segments.

One specimen has stool for many years in the collection of the American Entomological Society bearing a MS label in Mr. Cresson's handwriting. I have receiven ind itional specimen (pyrhostermum Kieffer) from C. F. Bakes.

## Fachus floridianus u. sp,

Q. S.-Black, neck, prothorax, coxe and entire legs, propodemm and spots on the abdomen red. Thorax and hind coxac coarsely reticulate.

Length 14 mm . Borer $12,5 \mathrm{~mm}$.
ㅇ.-Head back; impubescent, except clypus which is somewhat pubescent and ronghly sculptured, rest of lace closely covered with minute poneture con-
siderable smaller than the facets of the eses, giving the surface a doll lustre; mandibles bunt, rufous; edge of elypeas somewhat simate; autennar bark, first joint of flagellom clavate, longer than usual; head prolonged behind the cyes, abruply narrowed, margin reflexed. Neck long, rufons, closely transpersestriate. Prothorax, including proplenra, rufous, with an acute tooth on each side of the lateral anterior angles; the entire thorax and propodeum covered with coarse reticulations, interstices ahout the size of the ocelli; on the mosothoracic lobe these beome somewhat confluent. Wings stained dusky sellow. without violaceous reflection or very marked irridescence; nervures and sligma dark. Coxie and entire legs rufous, except the nosterior tarsi ; club wf tibia and spot on outside of posterior femora at apex black. Iropodenm rufous. Abdomen silky, moderately compressed; first segment rufons, with a black medial spot near the apex; second black, with a rufous spot on each side at the afrex: third biack, with a smaller rufous spot; remainder biack. Borer red; sheaths black. tipped with white.
§.-Similar to the $f$, but with the proplenre and sides of the propodemm less entirely red. Second segment of flagellum short.

A paratype from Havana, Cuba (. F. Baker), differ from the type in having entire pleure, borders of median lobe of mesonotum and the propodeam red.

This species is very distinct from any other that I know by the coarse reticulation on the thorax. It most nearly approaches puttersomu Melander and Brues.

Fernis fressonim w. sp.
Q.-Mead black; face very sparingly dotted with panctures much finer than the facets of the efes, slightly pubescent; mandibles acute, rufous, tip darker. shining, purtate, especially toward the base; clspeos hroad! emarginate, somewhat sinuate ; occiput finely transverse-striate, not interrupted and fairls regular, antenma black, first segment of the Hagellum scarcely clavate; head rather short behind the eves, hind margm acute. Nerk of medimm length. tan-versely wrinkled, with large interstices between the wrinkles. Thorix black; prothorax with an acute tooth on the lateral margin; medial mesothoracio lobe rather finely and closels tranvere-striate, with a few scattered punctures; sides of the thorax reticulate to ragulose, very slighty silvers sericeons: propodenm reticulate, black. Wings staned Fellowish, without violaceons reffertion or much irridescence; veins and stigma dark. Legs black; ring of white at baic of posterior tibise and tarsi, on the tibise broadened in front ; posterior coxar very finels transrerse-stafolate. Abdon. Tull silky black. abruptly truncate at apex. not greatly compressed ; two ferrug. us spots on eachs side near the middie subconflumt beneath.
§.-. Similar to female ; segments of antemat as in female, the second joint of fagellum twice lomger than fist. A little more robust than the female.

A robnst species. Three specimens. The front leas sometimos reddi.h.

Mab.-- Vanconver, Camada, Masamhusetts.

## F'ouns mevadien. sp .

Q.-Head black; face laterally silvery sericeons; finely and sparingly punetulate; mandibles subacute, rufous, tipped with black, punctate; clypeus short and hroad, shallowly simate, hroadly, not deepiy emarginate; vertex almost imperceptly punctulate, ruming into minutely transerse stiole; first scoment of flagellum clavate; head behind the ejes narrowed, so as to he subtriangular, posterior emargination narrow, the edge prominently subreflesed; head underneath silvery sericeous. Neck short, transversely wrinkled. Thorax black; sides strongly silvery sericens; prothorax with a tooth on the lateral angles; thorax entirely and closely covered with deep panctures, about half the size of the ocelli, but not confluent ; pronodeum coarsely reticulated. Wings hyaline, inridescent, without violaceous reflection; veins dark. Four anterior legs and cozar rufous; posterior black, except a small white band on the posterior tarsi near base aud on the posterior tibix near their hase, dilated in front; posterior coxa finely transverse-striolate. Abdomen red, exeept the extreme base and apex are black; scarcely compressed, tip subtruncate. Borer red, sheaths black, tipped with white.

Described from five specimens in the (tresson collection labelled in Mr. Cresson's writing "nevadensis n. sp." The only variation seems to be that one specimen has considerable fuscous on the abdomen. There is one specimen in the U. S. National museum collection that has the head behind the eyes a little less constricted. It is doubtfully referred to this species. The punctuation is a little more obscure, the posterior tibie rufous anteriorly. From New Mexico. Hub.-Nev., N. Mex. (Mesilla Park, May 7th, T. D. A. Cockerell). Type.-Collection of the American Eitomological Society.

Fremms perpiexis Cressson.
1864. Frenus perplexus Cress.. P. Proc. Ent. Soc. Plila., iii, p. 131.
1589. Gasternption perplexum Schletterer, O, Aun.d.k. k. Nath. Hofm. Wien, iv, p. 487.
ㅇ.-Heal black, face with a little silvery sericenus; punetation very minnte and rather close; mandibles polished, rufous; clypens sinnate, emarginate, occiput finely punctate, slightly trauserse-striate; antemme pubescent beyond the third segment of the flagellum, seape closely punctured; first segment of the flagellum short, subelavate; head narrowed behind the eres, posterior margin prominent, subreflexed. Neck medinm, closely punctate to subreticulate. I'rathoras with an acute tooth on the hateral margin; thomen entirely black; mesothorax ahove covered with several lage punctures at comsiderable intervals; sides of thoras more closely punctate to subreticulate; propodenm reticulate. Wings hyaline, slightly irvidescent, withont violaccons reflection; veins and stigma dark. Legs black; posterior eoxar finely frausversely striolate. Abdomen black at base and aper, medially ferruginous. Ovipositor red, sheaths hack, tipped with white. Length 1012 mm .
\}. -Similar to female, except that the antemate are entirely pubescent, and the second segment of the flagellum is half the length of the third ; the abdomen is back, with three fermginous spots on each side.

A distinct and interesting species．The thorax is often silury sericents，and the posterior tibise sometimes have an obscone white band at their have，broad in front．

## Vrenus arcus Couper.

1870. Feonus arca Couper, Camad. Eut., vol. ii. p. 110.
"Head black, glossy, impunctured; eyes black, round; antenne black, twoeighths of an inch long; thoras not so black as head: the sides beneath and between dark chestnut, interspersed with short fulvons hairs; wings fuliginous; nervures and stigma black; legs black, hairy; hase of the femora fulvous; abdomen bright red, with scattered fulvous hairs; ovipositor black, as long as the antennæ. Length 3 -8ths inch."

Mr. Couper mentions finding this in a cocoon under the bark of a tree.
"On the sth of Jamary last, while searching for hybermating Coleoptera in the woods near Ottawa, I had occasion to strip the batk of a decayed ash tree. mader which, anomg other insect store, l fomd a small transparent and curionsly formed cocoon contaning a larva of a fly which was at that time unknown to me. The cocoon was imbedded in the bark necupying what 1 am now led th believe the excavation made by a grub of Cerambex or some other coleopterons: batk borer * * *. The shape of the cocoon is oblong surromaled by a band and covered bs a thin pellucid lid, and the form resembes a small coflin. The
head of the insect was placed at the small end and the space in front of it is packed with minute particles of dust, evidently produced from the bark by the original occupier. Length of cocoon $\frac{5}{8}$ of an inch" (Couper).

## Hab.--Ottawa.

Focuus torrialus n. sp.
Black and reddish-brown, the plenre except mesopleuræ and the sides of the abdomen toward the ends of the segments somewhat more reddish; legs from base to knces reddish-brown; anterior and middle tibise and tarsi, except brown spot on tibiæ within, and apex of metatarsus and remaining tarsal segments white, posterior tibiæ with ring near base prolonged within, apical three-fourths of metatarsus and following two segments white; head, especially sides of face, and thorax silvery tomentose; wings hyaline; habitus very slender, with a long neck.
9.-Pusterior ocelli on a line with the back of the compond eses; occipnt not prolonged behind the eses, much tapered, the margin scarcely retlexed; face much narrowed below the antenna, impressed lines beneath the antenmæ diverging below, forming a somewhat elongate triangle, the base of which is the margin of the elypeus; clypeus shallowly emarginate; eres touching the posterior condyle of the mandibles; face, vertex and cheeks impunctate, dulty shining; antenne slightiy thickened berond the third segment, this considerably shorter than the fonrth. Neck rather longer than the head, minutely transversely wrinkled. Shoulders with a small sharp tooth; medial mesothoracie lobe covered with regnlar, well separated, moderate punctures, confloent along the parapsidal grooves, between these many much smaller ones; parapsidal and lateral grooves distinct ; scotellum senlptured similarly to the medial lobe of the mesonotum; sides lobes of mesonotam with fewer coarse punctures than the medial ; metaplenre and propodeum coarsely reticulate. losterior coxæ minutely transversely wrinkled ; apex of first segment of posterior trochanters completely separated from the base ber a transverse suture, so that the trochanters appoas three-segmented. Wings hyaline, with violaceons reflection; the cell $M_{4}$ frime gular, almost linenr, veins $M_{3}$ and $M_{+}$separating immediately upon sepuratiug from $M_{1}+2$.

Length 13.5 mm . forewing 6 mm . ; ovipositor 11.5.
§.-Similar to ?, the punctures somewhat thicker on mesonotum and occasionally confluent; spimele on middle of sixth dorsal segment large and conspienous.

Hab.-Mexico.
Types.-Collection American Entomological Society.

## AULACIN.E.

I have treated the North American species of this subfanily in a previous paper,* and the present, may be considered as in part supplementing, in part revising it.

The hind coxa of the males are normal, but in the females are

[^3]sculptured on the inner smface with a groove, at the base of which is a well-marked tooth, which in Pammegisehia and Aulncu: is greatly prolonged. I have not seen Aulacus, but according to Kieffer's figure, it is much less prolonged in Aulame than in I'ammegischia. These two genera are ahon mited with each other as well as with Interonlucus and fulucimus by the abounce of any veins except Se $+\mathrm{R}+\mathrm{M}$ in the hind wings (Fig. 69). Likewise in these fone genera the claws are simple or at most with two tecth beneath (Fig. 39). I'ammegischicu and Aniacus are parasitic on Diphydrin. The hosts of Iulucimus and Interuulucus are not known. All other genera so far as known are parasitic on the larse of Coleoptera. So that it seems as though these four genera may together form a distinct tribe in contrast to the remaining genera. There is hut one known species of Aulucus, although most members of the subfamily have been described as belonging to that genlus.

Deraiodontus Bradley is a pure symony of Pristuutucus Kieffer. In my former paper therefore substitute for Deraiodontus Bralley, Pristmulucus Kieffer, and for I'ristuulacus Kiefler, the new mame Verulacus.

The most generalized wing of the family is Aulacinus (Fig. 67). Note that $\mathrm{K}_{5}$ is entire; the base of $\mathrm{M}_{3} 4$ distant from $r$-m. (ell $\mathrm{M}_{4}$ is very small-rather a specialization, as is also the lose of venation in the hind wings. But the simple tarsal (law is a primitive character. The wing of Pammegischia onelletii (Fig. 68) was figurel to show the trouble that may arise from malformations: if we do not exereise care. There is an extra cell cut off from first $\mathrm{M}_{2}$, and $\mathrm{R}_{3}$ enters the stigna instead of being sparated from it by r. Both of these characters are monstrosities. The left ham wing of the type pecimen is normat. The wing of Pammeyischin ashmerdi (Fig. 69) is typical of the genus. A slight advance is shown in the partial - bose of $\mathrm{R}_{5}$. Apectalization is also shown in the prolongation of the coxse of the female. I'ammonish hice ant Aulucus may together be considered to form a sort of side branch. Going hack to Aulacimus we fimt Intoraularus. (Fig. T(t) the first -tep along another line, from which probably desecmed the remaining gencra. The base of $M_{3}$ is still distant from $r$-m. $i_{5}$ is entirely lost. The hind winge are as in P'ammegischiu. But the claw: have gamed a single tooth. The renation in the remaming
genera is always about the same, and is illustrated by Odontaulacus editus (Fig. 71). The hind wings are more generalized than in the preceding. In Semenovius they have two distinct cells. In the front wings the base of $\mathrm{M}_{3}$ a and r -m are approximate or joined. In the different genera we have specialization manifesting itself in an increase in the number of teeth on the tarsal claws, varying from two to four (Figs. 40-42).

The mouth-parts are shown in Figs. 24 and 25.
The arrangement of genera in the following table I believe to be as nearly natural as a linear grouping may be.

## TABLE TO THE GENERA OF AULACINE.

1. Posterior wings without venation, except $R+M$ (Fig. 69) ; claws simple, or with one or two teeth (AULACIN1)............................................ 2 .
Posterior wings with one or two closed cells (Fig. 71) ; claws with two or more teeth (Figs. 40-42) (Pristaulacini)
. (5).

6. Legs beyond the coxie, and the fac tawny.....................allipes ('resson.

Legs beyond the coxce brown, wnterior tibix and tarsi and posterior tarsi tawny. . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . .xiply divite Ashmead.

## 

The venation shown in Fig. 68 is abmormal. The left wing of the type shows venation similar to Fig. 69 .

Pannimegisehiat linequei Provancher.
Additional localities are as follows: Anglesea, New Jersey; Morgantown, W'est Virginia, coll. (Dr. A. D. Hopkins, accessions No. 7327 Hopk. W. Va., May 1897, from dead branches of hard maple infested by Jiphydria albicornis). The two specimens from West Virginia have the thorax and forehead entirely black.
[’ammegischian xiphydrite Asbmead.
A metatype is precisely like pullipes Cresson (type of weedi Ashmead) in size, hahitus and everything except the greater amount of brown on the legs. I think this species must be the female of pallipes. Lovei Ashmead, previous to seeing which, I had thought might occupy that position, is distinct.

In the type the ovipositor is lwoken; in the metatype it is 3 mm . long; the total length 5 mm .

Additional localities: Caroline to Harford, New York, June 15, 1904 , Dr. A. D. MacGillivray (metatype, in coll. Cornell Unir.). A specimen collected by Mr. Beutenmäller in the Black Mountains of North Carolina prohably belongs here; Muskoka, Ontario (E. P. Van Duzee).

Pammegischian ashmeadi $u$. sp. (Fig. 69).
Q.-Black; first abdominal segment except base, and base of second red ; the knees, tarsi, anterior tibiæ and middle tibise in front and at apex pale sellowish; rest of legs beyond the coxæ brown. Frontal crest distinct; forehead deeply and irregularly reticulate ; occipnt smooth, polished and impunctate ; medial mesothoracic lobe somewhat gibbons, with a shallow emargination marked laterally by the two anterior grooves, which are distinct. Projection on posterior coxie longer than in $P$. burquei; claws simple; posterior wings withont remation, except sic $+\mathrm{R}+\mathrm{M}$. Abdomen short and stout; ovipositor about 7 mm . long. Length 8 mm .

Mab.-Montreal, Quebec, one female.
Type.-In the author's collection.

## Pannmegiselnit nininesolat n. sp.

§. -Reldish tawny; forehead, occiput, dorsmm and propodeum black; apical fonr joints of the abdomen blackish, rest of the abdomen red. Forehead with several very prominent well separated and unbroken transverse wrinkles; the occiput also with distinct wrinkles, especially mesally. Mesonotum very shalfowly emarginate, the borders of the emarginations marked by the anterior grooves. P'osterior wings withont veins; claws simple. Lengin 7 mm .

Hab.-hake Vamillion, northern Mimesota, (). Iager.
Type.—U. S. Nat. Mus.

## INTERAELACUS b. gen.

## Type.-1. kiefterin. sp.

This genus is a sort of connecting link between the Aulacini and the Pristaulacin. The genus is entirely South American so far as I know. Besides the type, Iristumlucus cundatns and $I$ '. tricolor Szepligeti, and perhaps $P$. hamorthoidellus Westwood belong to this genus, as doubtless do other described species.

## Interandacus kistferi u. sp.

Q.-Black; four anterior knees and base of tarsi, hase of posterior tarsi and middle of the ragince white; anterior tibise brown. Forehead and oeciput with well-separated round deep punctures. rather regularly seattered over the surface: temples more finely and closely punctured; posterior ocelli nearer the compond eyes than eath other: hasal four antenal segments in the proportion of 3 3 5-10. Medial mesothoracic lobe gibbous, deeply emarginate, the sides very acute in front, strongly transersely carinate. Fosterior metatarms onethird longer than the remaining joints together; wings hyaline, except the apical margin is fu-cons. Petiole long and slender; abdomen slender; ovipositor 12 mm . long. Length 10 mm .

Hab.-Brazil.
Type and two paratypes in the collection of Cornell University.

## NEVEN©VIUN n. nom.

$=$ Anamfacus Semenov, nec. MacLeas (Coleop., 1825).
= semenoviu Kieffer, nec Weine (Coleop., les9).
Type.-Amatarnes sibiricola Semenov.
Kietter erect scmenoru* withont mentioning any species, hut doubtless intended to replace Anculucus Semenov, as the charaters given apply to that gemus. Unfortunately Semenomia is itself preoceupied, and another change becomes necersary.
(HONTMELIAUS Kieffer.
Typer-Aulacus ruftersis ('resson.
Semenov was conrect in allying Alulacus rufitarxis Creson with Anculucus Semenov. But Kieffer distinguishes them by the venation of the hind wings, erecting Odontanlucme for Anlacus minno Cresson and A. rufitursis Creson, neither being mentioned as type. We may call ruftorsis type, as that is the more distinct and common of the two.

In my former paper I suppresed Aulucus editus, ubdomimulis and bilobatus. Since.then I have examined some homdreds of : pecimens,
'Sper. Hym. d' Eur. (Andre), vii, bis, p. 38\%.
and have coneluded that they may be recognized. Although closely related and apparently intergrading, certain specimens being of questionable identity, they may for the most part be separated by the following table. Rufitarsis, editus, and minor are western, abdominulis and bilobatus eastern. Both east and west they seem to be the commonest species of the subfamily, especially editus and rufitarsis in the west.

1. Abdomen with the apical half black . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . (2).

Abdomen red, the very apex occasionally dusky or black ..................... (4).
2. Posterior femora and tibiæ dark brown; abdomen with the second and the apex of the first segments dull claret-red; wings clear hyaliue. Hab.

Legs black, except tarsi are yellowish; abdomen more of a brick-red; wings stained smoky. Hab.-Rocky Mountains and west.
rufitarsis Cresson, $\widehat{\delta}$.
Legs red or yellowish; abdomen brick-red or yellowish. Hab.-Washington and Nevada.
8. Legs obscurely yellowish or rufous; posterior tibiæ and tarsi brown ; species slender. . . . . . . . . . . . . . . . . . . . . . . . . . . . . . .nininir Cresson, 尽, ․․
Legs all yellowish; species more robust...................editist Cresson. $\hat{\text { of }}$
4. Legs all black, except posterior tarsi. Hab.-Colorado.
rufitarsis Cresson, ?
Legs, at least four anterior pairs, rufous............................. . . . . . . . (5).
5. Posterior femora black or dark brown. Hab.-Canada and New England.
abolonminalis Cresson, ?
Posterior femora and sometimes tibiæ red; wings often smokr, with violaceous reflection. Hab.-Nevada and California to British Culumbia.
editus Cresson,

Odontanlatus editus Cresson (Fig. 24).
Nevada; Washington (Easton, T. Kincaid; Blue Mountains, July 15, '96, coll. C. V. Piper) ; California (Santa Cruz Mountains); British Columbia (Revelstoke, Selkirk Mountains, 26 spec., collected by the author, July 8, '05.
©dontanlactus rufitirnis Cresson.
Coloralo; Washington (Easton, T. Kincaid).
OAlontanlatens abdonninalis Cresson.
Georgia; Canada; New Hampshire (Webster, coll. W. F. F'iske).
()alontanlacus bilabinfus l'rovancher (Fig. 25).

Canada (Terrebonne, P. Q., July 20, 1901, coll. C. .J. Oueliet); West Virginia (Dr. A. I). Mopkins).

## TIROPAULACUN 1 . gen.

Head quadrate; a distinct pit below the antenme on each side; clypeus mucronate, separated hy suture from the face; antennat 14 -segmented, the last segment fattened, obtusely truncate, concave above. Mesonotum forming a part of both cephalic and dorsal walls of the thorax, so that the insect appears slightly hamp-backed, but the medial lobe not very gibbous; promotmon without teeth on the anterior margin. In the front wings the base of the longitudinal sector of the free part of MI is wanting, as in most Ichnemmonidax, hut represented by a stump of a vein, the cells $R+1$ st $R_{1}$ and $M_{1}$ being thus partly united; the free part of $\mathrm{M}_{3-4}$ separating a greater distance than its own length basad of the posterior end of the radio-medial cross vein; the position of $R_{5}$ indicate by a bulla, and a trace of a stump where it formerly joined $\mathrm{M}_{1}$, which is some. what angled at that spot; hind wings with all veins obsolescent except $M$ and $\mathrm{M}_{1 \cdot 2}$ and $\mathrm{R}_{5}+\mathrm{M}_{1}$ and $\mathrm{R}_{4}+\mathrm{M}_{1}$. Claws with four distinct teeth beneath, and sometimes a scarcely defined fifth.

## Tropanlacers torrialus u. sp.

9.-Brown ; the antenne except pedicel and first and last four segments of the flagellum, entire head except sport below ocelli, legs except the coxa, trochanters, and middle of the femora of the posterior pair, petiole and vagine except apex rellow; tip of mandibles, apex of the antenne and of the vagine black. Anteriur half of front wings and apex deep brown, rest yellowish-hyaline except the margin, somewhat smoky; entire body clonhed with short yellow pubescence.

Head from above quadrate, the ocelli considerably forward of a line connecting the posterior margins of the compond eses; cispeus mucronate, a deep pit below each antenna; compound eres removed from the base of the mandibies b? more than the length of the pedicel; head impunctate, weakly shining: first three segments of the flagellum in the proportions of 3-4.5-4.1; flagellnm beyond the first segment corered with rows of whitish scales. Mesonotum searcely gibbous, mesally emarginate, transversely rugose, the parapsidal grooves distinct. scutellom with wrinkles concentric around its apes; propodeum reticulate; posterior coxe weakly wrinkled. Triangular spot at apex of $\mathrm{Cu}_{1}$, all of $\mathrm{M}_{3}$. first and second $\mathrm{M}_{2}, \mathrm{M}_{1}$ caudal third of $\mathrm{R}_{5}$ haif of $\mathrm{R}_{4}$ and two-thinds of $\mathrm{R}_{3}$, yellowish hyaline, the margin of $M_{1}$ and second $M_{2}$ stained somewhat smoky ; rest of front wing deep brown, posterior wings sellowish byaline, a faintly brownish mark along the upper and outer border, Cu and $\mathrm{Cu}_{1}$ obsolescent, ransverse sector of the free part of M somewhat so. Abdomen shom, clavate, petiole distinct. Length 10.5 mm . ; antenne 7 mm .; front wing 9 mm . ; ovipositor 7 mm .

One female, Brownsville, Texas, Jume, coll. Univ, of K゙ansas.
By its peculiarly marked wings this species is very diflerent in appearance from any other of onn nearetic Aubacinac, indeed, conning as it does from Brownsville, in the extreme south end of the exten-
sion of the tropical region into Texas, may be considered as a fundamentally neotropical species, an affinity further corroborated by its coloring.

I am indebted to Mr. Henry L. Viereck for permission to study and describe this form.

## IPIRISTAUHACUS Kieffer.

I think it will be best to group Oleisoprister, Neaulacus and Pristaulacus sen. str. together as subgenera of Kieffer's Pristaulacus

Pristaulacis (Oleisoprister) dentitus n. sp.
§.-Black; tarsi brown, apical half of petiole (more ventrally) and basal twothirds of second segment red. Head smooth and polished with only fine setigerous punctures. Medial mesothoracic lobe somewhat gibbous, shallowly emarginate; prothorax with a slight blunt irregular tooth on the antero-lateral angle. Posterior metatarsus one-eighth longer than the remaining joints together, three times as long as the secoud joint; wings byaline, except a large fuscons spot beneath the stigma. Petiole distinct but short. Length 9 mm .

The tooth on the lateral angles of the prothorax will distinguish this species from all others.

Hab.-Ormsby County, Nevarla, C. F. Baker.
Type.-In the coll. C. F. Baker, Para, Brazil.
Pristanlatus (Deisoprister) firmus Cresson.
The only example that I have seen besides the mique type is a female sent me by Prof. C. V. Piper from Mt. Rainier, Washington.

Pristinulacus (Oleisopristev) resutorivorus Westwood.
Olympia, Washington, one female.
Pristamlatus (Dleisoprister) ablootiii Westwood.
Washington, D. C.; Marruette, Michigan, April 7th.
fristaulatus (Oleisoprister) stigmaterms Cresson.
Missouri ; Norton's Landing, Cayuga Lake, New York, June 21st.

## NEAULACUS u. subgen.

Type.-Anlucu: occidentulis Cresson.
Coextensive with Pristalucus as nsed in my former paper.
Pristanlacus flavipes Kieffer, Arkiv. f. Zool., I, p. 559, probably belongs here.

Pristamiacus (Neanlatens) oceridentalis Cresson.
Blue Mountains, Washington, July 15th, three males, one fomale; Beulah, New Mexico, coll. Viereck; Idaho.

Convallis, Orecron, Jnly 21st.
Frisianlacus Neamlacus mencificus Cresson.
Corvallis, Oregon, July 15 th.
Pristinnlacinc Neanlinens finsciatus Say.
Michigan, coll. Townend; Cadet, Missouri, coll. J. C. Barlow; Pennsyvania (two apecimens in coll. A. E. S.); Marion Connty, Arkansas (.J. C. Bridwell).

IPRIN'IIULACIS Kieffer.
Type.-Pristanlucus chluponskiii Kieffer.
Embraces those species included under Deraiodontus in my former paper.

## TABLE TO THE SPECIES OF [RISTAULACCS

1. Wings dark violaceous. Black, except more or less of the legs, and in the male the apical baif of the antennz are yellow..violacens Bradley.
Wings hyaline or slightly clonded, sonetimes with fuscous spots and a violaceous reflection . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . ( ${ }_{\sim}^{*}$ ).
2 . Utimate tooth on the tarsal claw beneath shorter than the penultimate; medial mesothoracic lohe gibbons and emarginate. Black; apex of the

Ultimate tooth ou the taral claw longer than the penultimate fig. 42 ....(3).
2. Medial mesothoracic lohe strongly gibbous. . . . . . . . . . . . . . . . . . . . . . . . . . . . (4).

Medìial mesothoracic lobe not strongly gibbuus . . . . . . . . . . . . . . . . . . . . . . . . . 5).
4. Wings hyaline. without violaceons reflection. Abdomen black, except the first veutral segment sometimes dull rufous....... ....niger Shuckard.
Wings of the female showing strong riolacens reflection; mesoplenre shallowly punctured, wrinkled ahove. Abdomen rufous, marked with

5. Wings showing strong violaceous rethection in the female; much fuscous present in the basal portion, paler in the male; mesopleura deeply irregularly réticulated; petiole short. Legs black.
luscalatus Pradles.
Wings withont violaceous reflection, or more than a trace of fuscons in the basal portiou; petiole long; legs flarous.... Ilavicrurus Bradles.

Prigtanlitcus violaceus Bradley, Zeits, f. Hrm. u. Dipt., v, p, 26.
This species may be distinguished from the others by the dark violaceous wings.

## lpristanlacous hopkinsii n. sp.

Q.- Black; apex of petiole and legs beyond the coxie uniform dull red. Has the ultimate tooth on the tarsal claw shorter than the penultimate. Closely resembles Oleisoprister resutorivorns Westwowl, but has the middle lobe of the mesonotum gibbous and emarginate much more than in that species. Margin of pronotum has a share tooth.

Hab.-Kirbyville, Texas, November 11, '02, Dr. A. D. Hopkins.
Type and one paratype, accessions No. 1231d Hopkins, U. S., deposited in the author's collection ; another paratype in collection Amer. Ent. Soc.

Pristandacus niger Shuckard.
Lake Pleasant, New York, July 20, '87; Albany, New York, September 21, 1900 ; Joliette, P. Q., Can., July 24, C. .J. Ouellet.

Pristanlacus montanus Cresson.
From the Santa Cruz Mountains, California.
Pristaulacus finscalatus Bradley.
\}.-Last fonr segments of abdomen black; wings without violaceons reflertion, the fuscous bands present but paler, especially the basal ones.

Claremont, California, C. F. Baker; Los Angeles County, California (metatype, ㅇ).

Pristandacus flaviciuras Bradley.
The U.S. National Museum collection contains a metatype from Agric. Coll., Michigan; Keene Valley, Essex County, New York, July 24, 1890, collection New York State Museum.

## EVANIINE.

1887. Evaniinæ, Cameron, Biol. Centr. Amer., p. 422.

The prevalent color is black, and this is sometmes varied with red, less often with yellow and sometimes a little white on the legs or antennæ. The head, body and legs are covered with a short yellowish or whitish pubescence, sometimes thick enough to obscure the seulpture, especially on the metaveuter, producing on the sides, head and propodeum of some species a bright sllvery sheen.

The head is transverse to tranverse-quadrate, very different from the heal of either of the other two subfamilies; it is most like that of Aulacinse, hut when seen from the side is less convex in front, and pointed or attenuated above insteal of rommed; in the Fomina the head is long, oval, and so attached ats to nomally throw the face in plane with the dorsum ; in Evanimat the face is always at right angles to the plame of the dorsmm. Posteriorly the entire head is concare, usablly deeply so, and the rim where the concave posterior part meets the convex anterior is msmally accentmated by a little ridge marking what I have callerl the posterior angle of the occjpot and temples; in the Aulacinse it is somewhat simikar, but in the Foninse
the prosterior concavity is reduced to a small cup like pit in which the neck is inserted, and the rest of the posterion (in this case lower) portion is convex and not separated from the temples. Seen from ahove, that is looking squarely down on the vertex (Fig. 10, 13 and 15), the head of Evaniinse is transverse to almost transvere quadrate and shows a varying distance between the eyes and the posterior margin of the oeciput. The sides may be inflated, square or rombled behind the eves. The ocelli are three in mumber; the anterior one sometimes somewhat transverse. Whether or mot the posterior ones are nearer to each other or to the compomad eves is a character of specific value. The eyes from this view may he prominent or not. The profile of the head varies in shape (Figs. 9, 14. 16 and 17). It is nearly ahways broadest below the middle, and marrowed, even hlmotly pointed at the vertex. The forehead may be plain or convex. The eye is always more or less slanting, making the temples brondest below, and it is of varying length, extemiing in Eveniella culifornica (Fig. 9) scarcely below the insertion of the antemse, but usually much below this, never, however, very closely approaching the mandibles. From in front the head varies from round to nearly triangular, or may be somewhat oblong, as in Acontlinevania princeps and A. lonyigena, etc. The eyes from this position may or may not he prominent; their imer margins are parallel, or somewhat converging. The mandibles have one or more blunt lobes within. The elypens is nsmally mucronate or obtusely pointed, not separated from the face above, but sometimes set oft laterally by a short groove; together with the face it is often swollen or broadly convex. There may be a longitudinal carina in the middle of the face and one on each side, and frequently in in Evaniini a short longitndinal interantemal carina. The antemme (Figs. 55 and 59) are situatel at varying distances apant, usually about the height of the middle of the eyes, hut sometime: as low at the hase, depending more on the length of the eves than difference in the actual position of the antemme. The scape in Evaniinse and at least sometimes in Hyptiini is much longer in the female than in the male. The second joint is ordinarily very shom, sometimes mot so, and this I have always called the pedicel. I have comated the flagellum at begiming with the third joint, the relations of which to the fourth are of specific value. There are thirteen joints altogether in each sex. In the female the flagellom is
sometimes thickened, particularly in Semuomyia, where it is strongly incrassated beyond the middle, see Fig. 55. The forehead is more or less convex in Hyptimi, but in Evanine it is concave, forming a distinct basin in which the two antennæ are inserted, and this is bordered below and usually laterally by a distinct carina or rim.

I have studied the mouth-parts from glycerine mounts of all the gevera but two (PI. VIII), and find that the maxillary palpi are 5 jointed, the palpiger distinct, and the labial palpi usually 4 -jointed, in Myptia 3 .jointed (Fig. 37). In Evania and especially in Hyptia the third joint of the labial pajpi is strongly inflated, and sub-tri angular (Figs. 28 and 29); the labium in Evania is broally oval, highly chitinized and conceals the rather short ligula; this is also true in Hyptia, but in that genus the labium is broader, rather pearshaped; in Acanthinevonin (Figs. 26) it consists of two narrow chitinized plates, which do not conceal the long lingula; in Evaniella (Fig. 35) the arrangement is similar, but the labium is a little broader; in Szepligetella the ligula is long, but the labium broad as in Evanica.

The neck is short, shorter than in Aulacinæ and much shorter than in Fcenine, so that the head normally covers the collar or pronotum (Fig. 18). If we remove the head and look at the thorax from in front (Fig. 19), we will see the pronotum as an irregular transverse piece forming the upper and side margin of the cavity vacuated by the neck, extending down laterally in a narrow point almost to the coxa (Fig. 19). The upper margin is more or less arenate, sometimes nearly straight and extends back below the mesonotum to the tegule. The shoulders, spoken of as the humeral angles (Fig. 19), may be entirely rounded, or sharply angled, and this character is very useful in classification. Below the cavity of the neck, and somewhat depressed, are two oval sclerites, which represent the proplemre (Fig. 19), and adjoin the procoxat below; the latter are in juxtaposition (Fig. 19).

If we examine the dorsum from above we will see the mesonotum as a large piece, rounded in front and extending backward to behind the anterior wings, where a straight transverse suture separates it from the sentellum. The latter is indistinet in North Ameriean Hyptiae, so that the mesonotum and scutellmm superficially appear as one piece. The mesonotum is of varying degrees of convexity, hat never gibbous, ats in Anacine. The maximum number of
grooves on it are as follows : a regularly curved groove on each side extending from the posterior to the anterior margins, spoken of as the parapsidal groove: a short longitudinal groove on each side between these and the tegulae, called the lateral grooves: and two very short grooves in the middle extending backwards from the anterior margin, called the anterior grooves. These are all present in E. uppendiguster, and form good characters for separating species. The mesopleure (Fig. 18) are oblique rhomboidal sclerites, partially separated from the mesoventer only by an obscure groove. An oblique sulcus traverses it in which the femora of the middle legs, may be fitted, when drawn up, and which together with the posterior part is highly polished in Hyptia. Anterior to this sulcus the sclerite is rounded out and full, forming what I have called the anterior swelling. The entire venter is usually more finely punctured than the other sclerites. The middte cose occasionally are placed far posteriorly, thus prolonging the mesoventer; the latter is mesally divided by a longitudinal suture, and emls between the cosx in a bifurcate process or furcula. The middle coxse are placed wider apart than the posterior, but the ratio of the two distances varies in different species. The metaventer is similar, but undivided from the metapleure, and without a medial sims. The posterior coxa are more or less closely placed, and the furcula in which the metaventer ends is of primary specitic importance; the lohes or tynes may be mere knobs (as genemally in Hyptia), or may be elongate, parallel (Fig. 64) or divergent (Fig. 66i) processes. The metapleura (Fig. 18) is roughly triangular, with its apex beneath the posterior wings ; it is often not separated posteriorly from the propodeum. The scutellum is a large noarly quadrate piece. Directly behind it and sumk in a deep depresion, forming scarcely more than a transerse line, is a selerite that I have called the metanotum, although it may be the postscutellum (Figs. 62 and 63 ). If looked at from the side this selerite seems to form the bottom of a narow groove, which, in Evanime, has very steep walls, in Hyplimi these walls are more sloping, a difference illustrated by Figs. 62 and 63 .

The distance from the metanotmon to the insertion of the petiole varies, but is approximately and on the average a little less than the length of the petiole, and about the length of the soutellum; hehind this the propodeum is produced a short distance and then
slopes off more or less abruptly into the posterior face or truncature, which may be flat, convex or concave, with a mesal angle. The propodenm is almost always reticulate, except above the petiole, where it may be punctured or rugose. In the genus Hyptia the shape of the reticulations on the sides just behind and perhaps extending over the metapleure is of prime specific importance (Pl. V).

The abdomen in the female Evaniini is about the shape of an isosceles triangle, base uppermost, and the outer angle with the pygidium produced into a point from which the ovipositor may be exserted (Fig. 18). In the male it is marrowly oval. Always in Hyptia and usually in all Hyptiini the abdomen of the male and female are alike, round and without any visible sign of ovipositor ; often it is impossible to distinguish the sexes. In both tribes the petiole is long, flattened below, and often striate or punctured, especially on the sides; it is not enlarged apically and is distinctly separated from the rest of the abdomen. The abdomen proper is highly chitinized ; in every species I have seen, smooth, black and polished ; it is very strongly compressed; the ventral segments only narrowly exposed ; these also chitinized and forming a sharp mesal keel at the lower edge of the abdomen. The ovipositor is never exserted.

The posterior coxs are grooved above for the reception of the femora. In all genera except Hyptia, and probably Evaniellus, the posterior legs are very elongate (Fig. 60); in the former genus they are only the length of the body, and the posterior tibise are distinctly thickened at their apex (Fig. 61). In two genera the posterior legs hear numerons strong spines in rows ; also in Hyptia there are rows of very minute spines, visible only with favorable light and under a strong lens, or more distinct in one species. The posterior tibie are armed with two long spurs, and the proportion of the longer of these to the metatarsus (first tarsal joint) is of specific importance. The proportion of the metatarsas to the following joints is also important, hout is nearly fixed in Myptio. In all general there is a distinct tooth within the tansal claw (Figs. ft-it), and the shape and position of this and its angle with the outer ray is of specific value in some genera, but nearly constant in Hyptia. Sometimes as in Zencevania (Fig. 50) and Nemomymin Fig. 51) the daw is bifid, and the inner ray much stouter and longer than the outer.

The wings of the subfamily are of special interest, inasmuch as we find in them a very complete series showing specialization by atrophy, from the condition found in Evamia as the most generalized to that found in Evamiellus at the other end of the group. The wing of Evenice appendigaster ( Fig. 76) is as generalized as any I know of 'in the sabfamily, with the exception of a few which show $\mathrm{R}_{1}$ more distinctly (see Fig .75 ). C and $\mathrm{Sc}+\mathrm{R}+\mathrm{M}$ are separated as in Aulacinæ abd Gasteruptioninse, forming a distinct cell C ; $\mathrm{R}_{3}$ after separating from $\mathrm{R}_{4}$ hends either obtusely or acutely or at right angles upward, and reaches the margin from one-third to two-thirds the distance from the stigma to the apex, but the angle at which it heuds seems not to be entirely constant within a species. As has been stated $\mathrm{R}_{4}$ is present in the most genemazed type (Fig. 75 ), but it is always partly atrophied, and usnally there is only a stump or no trace at all of it left. $R_{5}$ is never present. II separates from $F$ whin or close to the stigma, mmming almost backward till it reaches m-cu when it turns at right angles; m-cu is thas very long, and the cell $\mathrm{R}+1$ st $\mathrm{R}_{1}$ is diamond shaped. But in Zenceramict (Figs. 80-81) M separates from $\mathrm{Sc}+\mathrm{R}$ ahout two thirds of the way from the base of the wing to the stigma, or the base of M is entirely wanting, if present it runs hackward a short distance and joins m-cu, this vein being much shorter than in Eermin, and contimuing in an unbroken curve with the longitudinal part of M. After $\mathrm{R}_{4}$ the next vein to become atrophied is $\mathrm{M}_{1-2}$ and $\mathrm{M}_{1}$ at its base, and later along its whole length together with mand the longitudinal part of $\mathrm{M}_{2}$ (Figs. 76-80). I trace of these may generally be seen except in Evoniellus, Iyptia, semarologustar and Semuomyin (Figs. 84-87) ; in Emmiscus (Fig. 82) the longitudinal part of the base of $M$ (from in con to separation of $\lambda_{3} 4$ ) is lost; Zen.evamiu (Figs. 80 and 81 ), which hat been described, seems to be the next modification, and along a different line, the only instance which involves moxification of the position rather than atrophy of the nervares. In Semurodogaster and Semeromyin $\mathrm{I}_{\mathrm{s}}$, all of M beyond m cu except a longitudinal vein representing a portion of $\mathrm{M}_{4}$ am $\lambda_{3}$, and except $M_{4} C u_{1}$, and $M_{1}\left(u_{1}+1 s t-2 n d-3 r d . d\right.$ are lost ; so that we have only three closed cells left, namely (\%, M and ('u - Cul ; the next step is in Myptiu (Fig. 86), where only C , Sc $+\mathrm{R}+\mathrm{M}$, the stigma, a trace of R and $\mathrm{K}_{\mathrm{s},}$ C 1 n and $\mathrm{M}_{1}$ remain. The forewings are also broaler than in the other genera, except

Senceodogaster. The climax of the series is reached in Evaniellus (Fig. 87), where only $\mathrm{C}, \mathrm{Sc}+\mathrm{R}+\mathrm{M}$ and the stigma remain. This genus is at the summit of the family so far as the specialization of its wings is concerned. The posterior wings of all the genera have an almost separated posterior lobe (Figs. 76 and 86); there is never more than $\mathrm{R}+\mathrm{M}$ present along the costal margin and another vein within, and frequently this latter vein is also lost. It probably is Cu and $\mathrm{M}_{4}$. The wings are hyaline, with the exceptions of a few exotic species.

In 1887 Cameron first recognized this subfamily ineluding in it Gasteruption (Furnus). The date on Cameron's paper is November. Almost simultaneously Cresson recognized the subfamily in his "Synopsis of the Hymenoptera North of Mexico," dated 1887, without statement of the month. The enpy before me was received by the Cornell Library, December 28, 1887, so that it is likely that Cameron's paper antedated Cresson's, as the later was probably mailed to Cornell immediately on publication. Kieffer also gives Cameron eredit for the subfamily. Schletterer in his monograph recognized the subfamily, and placed Gusteraption in Aulacine, instead of Evaniinæ, and Ashmead in Smith's "Catalogue of the Insects of New Jersey," 1900 , p. 563 , recognized it, but as including Gasteruption. In his "Classification of the Ichueumonoidea," 1901, Ashmead separated Gusteruption from the Evaniine, and in this last sense the subfamily was recognized in my paper on "North American Evaniidæ," Tr. Amer. Ent. Soc., 1901, and by Kiefter in the " Genera Inseetorum," 1902.

Up to the time of Schletterer's monograph of the fimily, three genera had been recognized, Evouia, Hyptiu and Brachyyaster. Dr. Schletterer threw these all together into the single genns Evania. Recently Kieffer has recognized a new genus, Zeurevania ; Szepligeti Evaniscus; and Enderlein Evaniellus: shortly before Enderlein ereeted Evaniellus I established an Evaniella, and here describe three other genera. Psendevmin is a misprint for Zensevania.

Evomia is of almost world wide distribution, being found in every region except the Anstralian, in which one species, perhaps alecidental, oceurs, and three others just over the boarder line from the Oriental. But Evenian "ppendiguster is believed to have spreal from Europe to all regions, and is everywhere one of the commonest -pecies.

Aconthinevania occurs chiefly in the Anstralian region, and also five species in the Malayan suluregion of the Oriental ; two African *pecies possibly helong here. There are about thirty-three species.

Of szepligetellu only one species is known, from the Hawaiian Islands.

Evoniscus occurs in the Neotropical regions, where there are three species.

Zencevan has two species in the Palearctic, two in the Ethiopian and two in the Oriental.

Evoniella is known certainly only from the United States, Central and South America, but many species at least South and Central American crealited to Evamin probably really belong here. There are five species recognized.

Semoromyiu occurs in the Neotropical with seventeen species.
Semorodoguster has but one species, European.
Hyptia has thirty-one species from the Nearctic and Neotropical regions.

Evaniellus has four species from the Neotropical.
As far as known all the genera are parasitic on the oothece of cockroaches.

As showing the distribution of the genera the table on the next page will be of interest. 'Thirteen species of uncertain generic position are omitted. Evanin appendigaster is counted only from Enrope, which is believed to he its original habitat.

## TABLE TO THE GENERA OF NORTH AMERICAN゙ EVANHN゙E.

1. Abdomen of the female distinctly triangular. the apex produced into a short process from which issues the ovipositor (Fig. 18) ; abdomen of the male more or less narrowly oval; antennæ inserted in a single distinctly impressed basin, bordered at least on the lower side by a ridge; nsually an inter-antemal carina present; metanotum as seen from the side more or less deeply depressed. sides of the depression abrupt (Fig. 6: ) , (Tribe Evanilni)................................................
Abdomen of the female nearly circular (rarely somewhat triangular), the apex not produced into a process (or rarely slightly produced in Evaniellu), abdomen of the male the same shape as in the female (sometimes oval in Eraniella); antenna not inserted in a distinctly impressed basin, without any cariua below them, rarels between them; metanotum as seen from the side less deeply depressed. the sides of the depression sloping gradually (Fig. 63), (Tribe Hrptini)............................ 3 ).
2. Front wings with the maximum number of veins found in the subfamily, except parts of $\mathrm{R}_{4}, \mathrm{M}_{1} \div 2, \mathrm{M}_{1}, \mathrm{M}_{2}$, and $m$ mar be more or less atrophied; labium modified into a highly chitinized pear-shaped puate which nearls covers and conceals the ligula (Figs. 20-29).

Evanian Fabricius.
3. Wings with seven completely closed cells (Fig. 83), bind legs long, exceeding the whole length of the insect ............... Evaniella Bradles.
Wings with only the costal cell completely closed (Fig. ©6) ; hind legs much shorter and stouter than in any other genus of the subfamily, not exceeding the total length of the body (Fig. 61) ......IIyptiat Illiger.

EVANIA Fabricius.
Ichneumon, Sphex, etc., auct.
1755. Evaniu Fabricius, Syst. Ent., p. 345.

## Type-Evanic appendiguster Linnaens.

The sape of the anteune of the female is much longer than in the male. The proportions in actual measurements of the antemal joints are surprisingly constant in the North American speeies. The labium is highly chitinized and broadly oval, dilated at the base, almost concealing the short ligula (Figs. 28 and 29). The labial palpi have the third joint greatly dilated and triangular. The forehead has an impressed basin in which the antenne are inserted, bordered by a distinct rim below; there is usually a short interantenual carina, and may be a mesal and two lateral earine on the clypeus. The sculpture of the face and mesmotum is of prime importance: in one of our North American species the face is closely striate, in the other with a very few small scattered puncthres.

The mesopleure do not show a distinctly smooth and polished
area. The groove for the reception of the midrle femora is not very deep. The sides of the propodemm are not peculiarly sculptured, as in Hyptia. The metanotum is sunk deeply between abrupt walls formed by the scutellum and propodeum (Fig. 62). The furcula forming the posterior border of the mesaventer is of great importance and may be with parallel or divergent lobes or tynes (Figs. 64 and 65).

The abdomen of the female is the shape of an isosceles triangle, the prgidium being produced into a projection which contains the ovipositor (Fig. 18). In the male the abdomen is oval.

The posterior legs are long (Fig. 60), and always without spines. The proportion of the longer tibial spur to the metatarsus is of importance, as also that of the metatarsus to joints two to four together. The shape of the tooth on the tarsal claw and its size and angle are of importance (Figs. 44 and 45).

The wings are as shown in Figs. 76 and 77.
The genus is the most generalizel of the subfamily. It is distributed throughout the word, except in the Australian region, where one, perhaps accidental, species is foumd, and three other: just over the border in the Island of Lombok. But Evania appendiguster, believed to be originally European, has been introduced into every country.

## TABLE TO THE NORTH AMERICAN SPECIES OF EV゙ANIA.

1. Face with only a few small punctures: tarsal claws with two rass placed so as to form an acute angle, the inner one shorter (Fig. 44) ; antenne inserted close together in a broad shallow basin, with an abrupt but scarcely ridged front margin .........apperndigasier Linnaens.
Face coarsely longitudinally striate; tarsal claw bearing a tooth within nearly at right angles to the outer ray (Fig. 45 ; antemae sitnated rather far apart in a deep and well-marked basin, the anterior and lateral margins of which are limited bs a distinct carina, with a sharp angle in the centre below the antenure ..................................

Evaniat appendigaster Limatus. (Figs. 13, 17, 1ヶ. 27, 25, 29, 14, 56, 60, 62, 76.

1841. Evania afinis fuillon, Ann. Soc. Ent. France, x, נ. 311.
§. ․-Entirely back. Covered with a vers fine and inconspicuous griseous pubescence. Face conrex below the antenne, smooth, a few punctulations scattered at considerable and irregular distances; antemne inserted close together in a broad but shallow basin, with an abrupt but scarcely ridged front margin, extending laterally almost to the eyes and posteriorls without definite limit to in front of the ocelli: vertex narrow; middle ocellus transerse; temples narrow above, wider towards the base of the eyes; eyes removed by more that half their length from the mandibles; antemse long, filiform, somewhat thickened in the female Fig. 56 ) ; arerage measurements as below:

Thoras above with a few round pits scattered sparingly over it, larger and better defined than those similarly scattered over the face; parapsidal grooves clearly defined; anterior grooves short; venter and sides of the thorax with larger and more deeply impressed round pits, distant from each other, hut growing denser posteriorls until on the propodeum they merge into coarse reticulation: metanotum sunk in a deep and narrow transverse groove; furcula with divergent trnes.

Middle cosat widels separated; posterior cosæ subapproximate, sparingly. finels, phnctured ; posterior tibia with the longer spur about one-third the length of the metatarsus (Fig. 60); the latter abont the length of the succeeding two joints united; claws large, two-thirds as long as the fourth taral joint, toothed. the rast slender, placed at acute angles with each other, the apical one much the longer (Fig. 44). Wings hyaline (Fig. 76), the free part of $R_{+}$wanting, sometimes a faint line indicating its position; $\mathrm{R}_{3}$ obtusels angled herond $\mathrm{R}_{4}$ : the base of $\mathrm{II}_{2}+_{2}$ usually more or less atrophied; hiud wings withontan open costal margin.

Abdomen of the male oval, two-thirds as broad as long; the petiole nearly as long as the remaining part; the second segment hut little larger than the first of the four succeeding fully exposed segment, which diminish in hreadth towards the afpex : abdomen of the female an isosceles, almost equilateral triangle with the apex caudad and the dorsal hypothenuse somewhat convex Fig. 1- : the petiole less than half the length of the dorsal hypothennse; the serond sroment but little broader than the first of the three following fully exposed segments: the apical segment produced into a short dorso-candad projecting process concealing the ovipositor.

* The reference given in schletterer and Dalla Torre to E. fluricurnis olis., Enesc. Meth. Insect, vi, !. 453 , is not to be fonnd, and should evidently be muculatr.

Hab.-Distributed throughout the world, and almost everywhere the most abumlant species. It is helieved to have originally inhabited Europe from whence it has become naturalized in almost all countries along with the Blattidæ on which it is parasitic. In the United States it seems chiefly confined to the east, and is especially common in some of the larger cities. Say's unicolor was from the Rocky Mountains, but we have no other records from that far west. It has never been taken here at Ithaca, nor have I seen specimens from north or west of here.

## Evania nribana n. sp.

(Figs. 45, 66, 77.)
§. \&.-Black. Sericeous promescent, especially the face and propodenm, shining silvery in certain lights. Face subconvex below the antenna, which are situated rather far apart in a deep and very well defined basin, the anterior and lateral margins of which are limited by a distinct ridge which starts from a central point on the face below the antemm, raming on each side outward and upward, to a short distance from the eyes, where it turns in ward again, beeoming lost before reaching the ocelli; another earina extends longitudinally between the antemat traversing the whole length of the basin; as thus defined, the hasin is narrower than in E. appendiguster; from somewhat within the lower angles of the eyes a gronve exteuds on each side to the inner angles of the mandibles, which, together with the carime above described, enclose a shield-shaped area embracing the entire face, which is subcoarsely and regularly longitudinally striate, the striac converging somewhat towards the apex (clypens), which appeas as a very small triangular smooth and polished piece; the temples are rongbly substriate, below the eyes the cheeks are striate similarly to the face, the striaconverging towards the face and mandibles; the vertex is covered with large punctures; the ocelli placed close together, the central ones much smailer than the other two, between the central and each lateral ocellus is a small smooth prominence partly surrounding each ocellns, part of which it at first appears to be; eyes small, prominent, removed by a little less than their length from the mandilles; temples narrow, wider at the base of the eyes; antenne filiform, somewhat thickened in the female; average measurements as below:

|  | Scape | Perl. | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | Flag. |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
|  | Total |  |  |  |  |  |  |  |  |  |  |  |  |  |
| § | mm. | .72 | .12 | .78 | .78 | .74 | .70 | .61 | .61 | .56 | .53 | .50 | .50 | .50 |

Thorax above like the vertex, roughly and rather irregularly covered with coarse punctures; the sides, venter, propodeum and posterior coxa punctate to shallowly reticnlate; anterior grooves not evident, lateral and parapsidal grooves very short and barely discernable; metanotum not very deeply samk, comparatively broad, forming a trausverse rather squarely cut trough; furenla with divergent tynes (Fig. 66).

Middle coxie rather cluse together; posterior coxe subapproxinate; the longer spur of the posterior tibie less than one-third the length of the metatarsus; the latter longer than the rest of the tarsus tugether; claws large, about two-thirds as long as the fourth tarsal joint, toothed, the rays rather stout, nearls at right angles, the outer one slightly larger (Fig. 45 , there is some variation in the size of the inner tontl in the paratypes, but the angle seems constant). Wings hyaline, or slightly clonded in the apical third; the veins dark in the basal part, becoming pale beyond the stigma; $R_{3}$, olotusely curred beyond $R_{4}$; free part of $R_{t}$ wanting; free part of $M_{1}$ and $M_{1} \quad$ z pale, their base wanting (Fig. 77) ; hind wings with an open costal margin.

Abdomen of the male long, narrow, oblong or oval, almost linear; petiole more than one-third its length, striate; the segments smooth, polisbed, second to seventh inclusive exposed. Abdomen of the female subtriangular, with the apical angle angle slighny produced into a short process containing the oripositor: petiole one-half the length of the abdomen, longitudinally striate; the segments smonth, polished; the second almost twice as broad as the third; the second, third, fourth and fifth segments fully exposed, the latter broadly emarginate dorsally, exposing a part of the sixth and seveuth segments, which form the process already described; edges of the last two segments and apex of the ovipositor finely ciliate. Length 7 mm .

This pretty silvery shining species is very different in appearance and characters from E. appendiguster, or any others that I know. The most obvions characters are the striation of the face and the narrow abdomen of the males, but there are many other important differences. In all I have seen over eight males and seven females.

Five of the males were collected by Mr. Witmer Stome on the windows of his house in Philadelphia. As all the other opecimens have alon been taken in large cities, I have applied to it the name mbonu. Mr. Liebeck sends me five more specimens taken on the windows of a house in Philadelphia. It is of course possible that it may represent another exotic species, migrating similarly to $E$. oppendigaster. The front lears and antense are sometimes more or less pale.

Hab.-Philadehphia, Pa., August 5th (Mr. Stone) ; Wahhington. I). C., July 26, 1900; New Yook and Brooklyn, N. Y. (Messrs. Daecke, Brues and Franck).

Types.-Type ô in the collection of the Amoricam Entomological society. Type of in the anthor's collection. Three paratypes ( 3) in the collection of the American Entomological society. Two paratypes ( $\delta$ ) in the collection of U.S. Nat. Mus. Paratypes in the Amer. Mus. Nat. Hist.

## EVANELLLA Bradley.

Eunia Auctores, ad partem.
1905. Eveniella Bradley, Can. Ent., Febrnary, xxxvii. p. 63.

Type.-Evrmia unicolor Ash. [nec Say] EVaniella semuodu n. sp.
The labium (Fig. 35) is narrowly oval, not concealing the ligula ; the third joint of the labial palpi is ovoid, not triangular, longer than broad; the eyes are in E. culifornica (Fig. 9) extremely small, so that they do not reach much below the base of the antemme, normally they are longer (Fig. 16); the antennse are filiform, situated on a convexity of the forehead, or if in a slight concavity there is at least no distinct rim below.

The metapleurse have at most a polished spot on the upper corner, often none at all; the sides of the propodeum are not peculiarly sculptured; the furcula is usually with more or less divergent short tynes, often obscured by vestiture.

The posterior legs are long, and without spines.
The wings in all species known to me are hyaline; and the veins $\mathrm{R}_{4}, \mathrm{M}$ beyond $\mathrm{m} \cdot \mathrm{cu}, \mathrm{M}_{1-2}, \mathrm{M}_{1}, \mathrm{M}_{2}$ and m are wanting, or present. only as a trace (Fig. 83).

The shape of the abdomen is more or less intermediate between Evaniini and Hyptimi. The abdomen of the female is quite or nearly round, never distinctly triangular, but in one specimen is nearly so; there is sometimes a slight production of the prgidium into a point containing the ovipositor. The abdomen of the male varies from round to narrowly oval (E. neomexicana).

So far there are only five species of the genns known, three from North America, one from Cuba and one from British Gniana. But it is probable that many, at least of the South and Central American, Evanise really belong here.

## TABLE TO THE NORTH AMERICAN Slectes OF EVANIELLA.

1. Eyes very small, scarcely reachang below the insertion of the antennar (Fig. $9)$; head, face and dorsum polished and almost impunctate.
ealiformieat Ashmead.
Eyes large, reaching far below the insertion of the antemme (Fig. 16) ; Head, face and dorsum more or less punctured.
... (3.
2. Head small, narrower than the thorax; head, face and dorsm finely punctured; inner tooth of the tarsal claw much shorter than the onter.
neonmexicinint Ashmead.
Head large, broader than the thorax ; head, face in part, and dorsum coarsely punctured; rays of the tarsal claws nearly equal (Fig. 49).
semacodiat n. sp.

Evanicllat calilornicat Ashmead.
(Fig. 9.)
1901. Ermia californica Ashmead, Can. Ent., xxxiii, p. 30:.
1905. Evaniplla culifornicer Dradles. Can. Ent., xxxvii, p. 64.
§.-Brown, imphescent. Head large, broader than the thorax; face smonth. shining, with only a few irregnlar and scarcels impressed punctalations: a deeply impressed line extending on each side between the antenne downward and outward in an irregular curve to the mandibles, forming a vers narow strongly mucronate clypens; mandibles broad; antenne inserted close together. far distant from the eres. which are very small, oval, and placed their full length from the mandibles (Fig. 91, their base barels extending below the insertion of the antennæ; cheeks very broad, polished.

Dorsum smooth, polished, minutely sparingly punctulate; propodeum in front of the insertion of the petiole similats sculptured, rest of the propodeum and pleure pitted or reticulate; metanotum situated in a transverse broad and shallow groove. Ponterior coxe smooth; metatarsus somewhat longer than the three following joints united; the claws with a single distinct rap, the inner ras being reduced to a very small tooth. Wings short, only reaching the tip of the abdomen, hyaline; reins brown; $\mathrm{R}_{3}$ obtusely curved; $\mathrm{R}_{4}$ wanting; $\mathrm{M}_{1} 2_{2}, \mathrm{M}_{1}$, m, and $\mathrm{M}_{2}$ indistinct.

I'etiole short, smonth, about one-fourth the length of the abdomen; the latter subovoid : segments $\underset{\sim}{2}-7$ exposed, segment 2 a litile wider than 3 .

> Mab. - Califonia (Natoma, Match 3, 1885 ).
> Type.-Collection of the U. S. Nat. Mus., 6081 (one male).

Nvaniella neonmeveanat Ahmead.
(Fig. ~3.)
1901. Erenit neomcxicun, Ashmead, Can, Ent., xxxiii, p. 302.
1905. Eramiella neomexicana Bradles. 1. c., p. 302.
b.- Black, the lower parts of the metaplenre and the propodenm below the petiole red. Finels pubertlent. Head small, narrower than the thorax ; face shallowly, closels punctulate, the punctures somewhat confluent; antennid appoximate, inserted on a consexits of the front; a groove extending from without the antenne downward and slightly inwarl to either side of the els pens; vertex rounded, elosely punctulate, not confluent; cheeks and temples very harrow and almost linear, smooth and polished, with a few scattered punctures; eses large, oval, removed hy one-third their length from the mandihles.

Dorsum with distant iarge round puncures; plenre similarly and venter more sparingly punctured; upper angles of mesophenre smonth, polished, impunctured ; propodeum coarsely reticulate: metanotum comparatively broad in a shallow transverse, curved groove. Posterior enxie approximate prongs of the foreula subavergent, the larger tibial spar more than half the length of the metatarsus, the latter nearly as long as the three following joints mited ; last joint nearly as long as the third; chas two-thirds as large as the fourth tarsal joint, slender; rass at acoute angles, the inner (basal) ray wuch the shorter. Wings long, extending considerably berond the tip of the abdomen, lyaline; the stigma dark, many of the veins more or less faint; $M_{1}, M_{1}, m$ and the longitudinal part of $\mathrm{JH}_{2}$ visible as mere traces; F : obtusely angled.

Abdomen long and narrow; the petiole punctulate, two-thisds the lengtlo of the abdomen. Segments $2-7$ fully exposed, the secoud but little wider than the third.

Hab.-New Mexico, Las Cruces, Sept. 9th (T. D. A. Cockerell). Types.-U. S. Nat. Mus., No. 6080 (2 males).

Cuaniellat semaedrat n. sp.
(Figs. 11, 16, 35 and 49.)
1857. ? Hyptia dorsalis Cresson, Cat. Hym. N. A..1857, p. 182.
1901. Eveniu unicolor Ashmead, ad partem, Can. Ent., xxxiii, p. 304, nec Say.
§. ㅇ.-Black, the thorax, petiole, scape and face sometimes more or less red. Finely pubescent. Face sparingly punctured, edge of the clypeus smooth, acute; antennæ inserted close together on a conrexity of the face, more than the leagth of their first two joints from the ocelli; front above the antennæ coarselp, vertex very coarsely punctured ; ocelli large, distant; cheeks narrow, almost as wide at the apex as at the base of the eyes; eyes large, oval, removed by about one-fourth their leugth from the mandibles.

Thorax coarsely and thickly punctured ; puoctures smaller on the sides and venter; propodeum reticulate, a polished spot on the pleuræ; parapsidal grooves wanting; metanotum not very narrow, in a slight transverse impression. Middle coxa moderately distant, posterior ones approximate; the prongs of the furcula parallel; the posterior coxe coarsely punctured; the longer tibial spur little less than ove-half as long as the metatarsus; the latter about as long as the following three joiuts united; claws small, about two-thirds the length of the fourth tarsal joint, bifid; the rays about equal, at acute angles, the onter (apical) ray sometimes much less stout than the other (Fig. 49). Wings hyaline, veins $\mathrm{R}_{4}, \mathrm{M}_{1}+2, \mathrm{M}_{1}, \mathrm{M}_{2}$ and m wanting, their position indicated by a faint trace; $\mathrm{R}_{3}$ obtusely angled.

In the male the petiole is smooth; about two-thirds the length of the broadly oval, nearly orbicular, polished abdomen; segments $2-6$ inclusive fully exposed; the third about two-thirds the width of the second. In the female the slightly pitted petiole is about one-half the length of the nearly orbicular, obliquely truncate, polished abdomen ; segments $2-5$ inclusive fully exposed, the second making up about one-third of the exposed area, almost three times as wide as the third segment.

The color of this species is very variable. It is barely possible that two species may be ineluded, the one of northern distribution and black in color, the other southern and with more red. The color, however, intergrades, and I can find absolutely no structural difference that will separate them. I have in all before me eight specimens, all from the United States National Museum collection. Four specimens are hack entirely, except with forelegs testaceons beyond the trochanters, and two of them have some reddish on the dorsum. One specimen is mixed with reddish brown all over the thorax and legs, and the base of the antenne, and the apex of the
petiole white; another has the first five joints of the antenne and the front and middle leg. brown, the trochanters and apex of petiole white, and the upper part of the thomax red; another the scape. lower part of the face, and npper part of thorax red, and the front legs bownish; two others hase the upper part of the thomax red, and the apex of the petiole white.

In the "Camadian Entomologist," rol. xxxiii, p. 304, Dr. Ashmead state that he has recently recognized Evaniu micolor Say as distinct from appendigaster, differing in punctuation. From the labels on his specimens it is evident that he refers to the northern or black form of this species, semuoda, which differs very marked! from appendigaster, but very certamly belongs here and not to Evaniu. In the "Canadian Entomologist," vol. xxxvii, 1. 64. I state in speaking of Evaniellu, "Here also belongs and stands as type the species which Dr. Ashmead calls unicolor Say, but is not that species. Say's deseription applies to E. "ppendiguster, which could easily have spread into the interior with the eally settlers, inasmuch as it is parasitic on cockroaches."

After receiving a letter from Dr. Ashmead assuring me of his conviction as to the eorrectness of his determination, I lookel over the matter again and came to the conclasion that he was right, and so wrote to him. Inasmuch as there was doubt concerning the identification, and since the type was destroyed, it seemed to me right to follow his determination. But recently it has seemed to be so imposible to identify the specimens in question with say's description, that I have decided to follow my former course and describe it as new, leaving Say's unicolor as ayonym of "ppendigaster, or ats a species which has not since been collected and which may yet come to light. I follow this couree with great regret, not only hecause I do not wish to add maneccesarily to momenclature, but because could I conscientiouly do oo. I hould prefer to follow the judgment of an entomologist as expernenced as is Dr. Ashmearl.

Say's description of unicolor is as follows, the italics are my own:
"Entirely black, immaculate, slightly sericeous. Inhahits the United states. Antenme as long as the bod? ; jalpi piceous; thorus with rery fer smull punctures: metathorax [propodeum] densely punctured; wings lyaline, nervnies fuscous: " distinct nervure passes from the dividing nervore of the cubital and discoidul cellulex to the posterior margin of the wing: abdomen much compressed; impunctured. polished oval, rather fonger than the petiole; posterior feet elongated. Lethgth more than three-tenths of an inch.
"The proportions of the petiole, abdomen and posterior feet of this insect are nearly the same with those of appendigustor Fabr. l obtained a specimen near the Rocky Mountains, and it is also found in Penmsylvania. The additional nervure is sometimes connected with the radial cellule by a faint, transerse nervure, so as to form a second cubital cellule."

In semuoda the thorax is coarsely and thickly punctured; in appendigaster it has very few small punctures. In semmoda the mesopleurat have the upper halff smooth, a character that would not likely have been overlooked by Say; in appendiguster the upper part of the mesopleure is only slightly less punctured than the lower part. It is characteristic of semtrotu as well as other species of Evaniella that the "nervure passing from the dividing nervure of the cubital and discoidal cellules to the posterior margin of the wing" $\left(\mathrm{M}_{1+2}\right.$ and $\left.\mathrm{M}_{1}\right)$ as well as the "faint transverse nervure" comecting it with the radial cellule ( $\mathrm{R}_{1}$ ), "so as to form a second cubital cellule," and also m-cu and M are always and invariably atrophied (Fig. 83). In appendiguster and other species of Evamia these veins are present, just as described in the description of umicolor, but in occasional specimens of appendiguster only, so far as I have observed, is $\mathrm{R}_{4}$ present, and then always partly atrophied, so as to appear', as Say says, as a "faint transverse nervure." 'The proportions of the posterior feet of semorodu are not the same as in appendiguster. In semooda the metatarsus is about as long as joints $2+3+4$ together, in uppendigaster only as joints $2+3$. The joint bearing the claws is much longer in appendiguster than in semuoda.

Inasmuch as appendigaster was a Emropean species, it is highly probable that Say would not have identified his specimens with it even if they agreed. He points ont no difference between micolor and appendigaster, and we have no evidence that he knew appendigrester from anything except deseription. On the other hand it is possible that micolor maty represent a mative American species which is at present unknown to us. I have secon no secimen of "ppendiguster or somuorlu from west of Georgia and (Ohio, whereas Say described muieolor from the Rocky Momitains.

The red form of semerodu has been in collections as .Evmiu dorsulis W estwood.

Hub.-Massuchusetts (Woorls Holl, (: 'T. Brues) ; New derses

## Evemiu Fabricius, et al.

1007. Hyptia Illiger, Rossi, Fauna Etrusca, ii, p. ~2.

1-41. Hyptirm Shuckard, Entom., i, p. 120.
1859. Evemia Schlelterer, Ann. d. k. k. nath. Hofm., Wien, iv, p. 118.

Type.-Evernia petiolata Fabricias.
The color is usually black, but may be more or less red or yellow; the anterior and often middle legs are sometimes pale or hrown, but the color is variable within the species. Clothed with a white or yellowish sparse pubescence, sometimes becoming so thick on the metarenter and coxse as to conceal the punctation. The head seen from above is transverse to transverse-quadrate, the anterior margin between the eyes appearing from such a view more or les convex, sometimes with a mesal emargination in which are placed the antemæ (Fig. 12). In profile the head varies from narow to broad, maally widest at or below the antemse, either flat or more or less pointerl above the ever; the latter are somewhat oblique, and the malar space is generally ahout one-half atolog as the eves ; the mandibles are short, and have a hlunt tooth within; the clypeus is pointed in the middle, sometimes set off laterally by a short indistinct groove; from the upper margin of the base of the mandibles a carina is usially present rumning to the base of the eve, and then upwarl parallel to and slighty separated from the inner margin of the eye, to varying height, separating the face from the cheek: ; the clypeus and face are usually somewhat prominent or gibbons; the forehead is flat or convex, and the antemate are not inserted in a hasin, nor are there any carine between or around them ; they are 13 -jointed and are either filiform, gradually and evenly thickened (Fig. 57), or short and strongly thickened beyond the loase of the flagellum (Fig. 58) ; these characters and the proportions of the scape to joints three and four together, and of the pealicel to joint three, I have fomb of specific value, although these distinctions are doubtles to a certain extent only sexual. The labium (Figes 37 and 38 , consists of a large, highly chitinized, broad, pear-shaped piece, heneath which the ligula is concealed and the palpi originate; the lahial palpi are 3-jointed, the terminal joint broadened, but not
as much is the third joint ; the palpiger distinct. The head behind the eyes and vertex is more or less narrowed, a carina of varying distinctness separating it from the gular regions.

The neck is short. The pronotum (Fig. 19) consists of a transverse vertical piece, constricted in the middle and usually smooth and polished; the lower edge is more or less produced forward into a short transverse collar; the humeral angles (Fig. 19) are prominent or rounded; the upper edge is emarginate in the centre, the mesonotum fitting into the emargination ; the proplemre and venter are not distinct, but small and concealed beneath the head, as is alway the case in the subfamily (Fig. 19). The mesonotum and scutellum form together a more or less convex area, and are separated from each other by a transverse straight suture that is often not plain; the anterior and lateral grooves are absent, the parapsidal grooves are not present in any species in our fama, or at least not more than a trace of them anteriorly ; in West Indian and other exotic species they are distinct, hut when so are usually placed a little nearer the middle than in Evaniu; the mesopleure have a highly polished impunctate or minutely punctulate area occupying more or less of their upper surface (Figs. 1, 6 and 7) ; this area is generally broken above by a circular pitted area, and has usually some irregular pits in the middle; its shape and extent, and the depth and shape of a large oblique fossa or depresion traversing the forward part of it, and forming a receptacle for the femora are characters of specific importance; anterior to the depression the plemre are swollen into an oblique broadly rounded ridge, the punctation of which is usually sparser than on the dorsum, but similar to the venter, from which it is not separated. This area I have spoken of as the anterior swelling of the mesoplenra. The metanotum (Fig. 6.3) is a very narow transverse strip, depressed between the scutellum and propodeum, the edges of which form gradually soping walls for it (Fig. 6:3). On the metaplense there is anteriorly a very narow punctared area, intermpted mesally, hehind which there is an ohlique well maked carina, parallel to and behind this carina is a broal foss of varying depth, aml the nature of the reticulations in this forsa and on the propordemm just behind it is of great specific importance ( Pl. V ) ; these may be long and narrow with few or no cross hars, or nearly square, and there may be from one to three rows ; one or two oblique carime may be presont, one
on the anterior edge of the region; the other near the poterior edge; behind this area of modified reticulations the entire propodeum is hexagonally reticulate, except above the petiole, where it is punctured or otherwise seulptured.

The hind legs are much shorter than in the other genera (Fig. 61, about equalling the whole length of the insect; the coxise have an oblique groove without, much deeper than in Eamiu. The tibise and sometimes the tarsi have among the pubescence rows of fine yellow spines; these are usually difficult to detect, and I have never seen any in which they are prominent, as they are in Acruthinemomiu, in which they are black and very much more abundant. $H$. amazonica schletterer is sait to have the spinewdistinct. The tibia is thickened a little toward the apex; the longer of the two apical -purs varies in the different species from les to more than one-half' the length of the metatarsus; the latter is longer than joints $2-4$ taken together, and upon how much longer depend some specific distinctions; the tarsal claw is of moderate on small size, with a single tooth within (Fig. 54), shorter than the apieal ray, and at a little less than a right angle to it ; the size and angle of the tooth does not seem to differ in the genus, and hence offers no character for -pecific distinctions.

The wings are hyaline, sometimes with a milky lustre, and there are present in the front wing (Fig. \&6) only reins $\mathrm{C}, \mathrm{Sc}+\mathrm{R}+\mathrm{M}$. the stigma, $\mathrm{Cu}, \mathrm{C} n_{1}$, and $\mathrm{M}_{4}$; where the t wo latter join a short crospiece indicates the original position of the base of m cu and $\mathrm{Cu}_{1}+$ $\mathrm{M}_{4}$. Faint lines indieate the original position of some of the now atrophied veins, arranged as: in Ememiu. The hind wings have only part of the vein $\mathrm{K}+\mathrm{M}$ present.

The senpture of the petiole is a matter of prime importance; there is usually a tendency toward ohligue ridging, at least alongr the lower part of the sides, hut above it may be nearly smooth with only a few punctures, or may be finely longitudinally striate; the length of the petiole is usablly abont equal to that of the abobomen. or sometimes less. The abronen is orbicular, alike in the twosexes. black, smooth and polished; the serond segment extends about $t$ wothirds its entire length, the thime segment is also broad, and the remaning segments are very marowly, when at all, exposed. The ovipositor is bot exserted, nor are the chaspers of the male evident. $\therefore$ o that it i- usually impossible to letermine the sex without disere-
tion. For this reason I have been frequently obliged to omit statement of the sex in the descriptions that follow. Judging from the other genera it may be inferred that those with more filiform antemne and shorter scape are males. Some of the published descriptions have certainly erroneously stated the sex.

The largest species that I know is about the size of Evamia appendiguster, the smallest measures 2.5 mm . Hyptio is the most specialized genus of Evaniina, except Evamiellus, as is evident primarly from the wings, where the climax of atrophy is reached, almost all the veins having disappeared. The mouth-parts and thoracie structures show further specialization along the lines followed by Evania, and I think it not improbable that even the shortness of the hind legs indicates greater specialization, although in the opposite direction, than the extreme length of the same in the other genera. Further I believe the genus to be one that is undergoing active modification today, judging from the fact than in our North American species, which I have studied very carefully, it is difficult to find any two specimens which do not differ more or less in one or more characters, although perhaps to an extent that would not be noticeable to one not very familiar with the group.

Iyptia is confinell to the Americas, and reaches its highest development in the tropics, where future collection may be expected to yield a very large number of new species.

## TAble to the north american species of hyptia.

1. Flagellum distinetly thickened beyond the middle, taperiug again to ward the apex, giving the antenna a distinctly clavate appearance, the joints in the thickened portion often scarcely longer than broad (Fig. 58)..(2).
Flagellum filiform or slightly and evenly thickened, the joints distinctly longer than broad (Fig. 57)
2. Petiole more or less distinctly punctured, slightly or not at all striate $\cdots(3)$. Petiole finely and very distinctly sublongitndinally striate.
havpyoides n. sp. (?).
3. Sides of the propodeum sculptured as in Fig. S; species black.
miylacridominnes m. sp.
Sides of the propodeum sculptured as in Fig. 6; species usually more or less red . . . . . . . . . . . . . . . . . . . . . . . . . . . thorancicat Blanchard ( $q$ ) .
4. Scape one-quarter or less longer than segments $3+4 \ldots \ldots . .$.

Scape distinctly more than one-balf longer than segments $3+4$; petiole thickly set all over with conrse punctures, between which are interrupted strix................................... retichlatsasis (Q).
5. Punctures evenly placed on the vertex and mesonotmm, abont their diameter's length apart. Jength $2.8 \mathrm{~mm} . . . .$.
Punctures much rougher, more closely placed. Length 6 mm , or more ...(6).
6. Sides of the propodeum with long parallel bars and narrow interstices (Figs. 2 and 3)................................................. . . . . . . . . . . . . . 11 ).
sides of the propodeum not susculptured... . . . . . . . . . . . . . . . . . . . . . . . . . . . (r) . r).
7. Sides of the propodeum with a distinct second obligue earina, between which and the first the area is depressed and the interstices lengthened, the bars parallel and often weak (Figs. 1, 4 and 7 ); petiole on the side with numerous deep punctures, wrinkles indistinct or none.......(9).
Interstices on the sides of the propodeum broken up into three rows of squares (Figs. 5 and 6 $\qquad$
s. Scape between one-fifth and one-quarter longer than segments $3+4$; petiole coarsely obliquely wrinkled, less distinctly ahove: interstices on the side of the propodeum rectangular, in three rows (Fig. 5). Black.
texanat $n$. sp.
Scape less than one-fifth longer than segments $3+1$; petiole with few irreg. ular shallow punctures; anterior swelling of the mesopleure closely and coarsely punctured ; color usually more or less red.
thoracie:a Blanchard ( $\hat{b}$ ).
9. Anterior swelling of the mesopleure smooth, with only a vely few minute punctulations; face coarsely and roughls seulptured; the punctures on the forehead leaving between them Hat polished rims; petiole punctured, without wrinkles on the sides . . . . . . . ......... ..... (10).
Anterior swelling of the mesopleure with a number of coarse punctures; face roughly but much more fincly and brokenly sculptured : punctures on the forehead so close as to leave only a narrow convex opraque ridge between them; propodeum as in Fig. 7 ; petiole thickly set all over witb coarse panctures, a few strie toward the sides, aud very fine strix between the punctures. Black.........reticulatin Sas ( $\}$ ).
10. Black; tibial spur less than one-half as long as the metatarsus: sides of the propodeum sculptured as in Fig. 4.........................toides n. sp. More or less red ; thibial spur over three-fifths as long as the metatarsus; propodeum sculptured as in Fig. 1...............prosetetheirat n. sp.
11. Petiole roughly obliquely to longitudinally striate above and beluw, punctures. often coarse, among the very fine strixe color entirely blate (Fig. 3)
haripyoides n. su. ( $\delta$ ). letiole nearly smooth, with a few small punctures and short striee on the sides helow ; color more or less red (Fig. :~)...lyypliogratiris n. sp.

## Hypliat latroyoirles $n$. sp.

(Figs. 3, 12, 54, 57, 5 s and 61 ).
1-87: II!ptia reticulatu Cresson, ad partem, List Hym. N. A., p, 182.
§. Y.-Brown; anterior legs and middle tarsi lighter, subtestacenns. Head and body elothed with gellowish hairs, especially thick on the renter and posterior coxal almost obscuring the furcula and sentpture of that region. Head secon from above (Fig. 12) transerse, nearls quadrate, strongly convex in front between the eres ; pace behind the eyes rather small : posterior angles romoded: posterior margin truncate, reflexed. Profile rather broad, rounded above; forehead slightly convex: ege very slightly obligue; temples widened below; malar space ( .43 mm .) two-third as long as the eyes ( .63 mm .) ; cheeks incurved below. su that the base of the mandibles is scarcely visible from the side. Face from
in front a little longer than in reliculutu, somewhat truncate below, the eyes sligbtly prominent; no antennal basin; mandibles deeply punctured at their base; palpi pale; clypeus not separated laterally by groove, the checks separated from the face by a poorls defined carina extending from the upper angle of the base of the mandibles outward and upward to the base of the eyes, then along the inner margin of the eyes to their summit; the middle of the face with the clspens forming a slightly gibbous area without distinct boundary; face. forehead, vertex, temples and cheeks rather mote closely and coarsely punchured than in recticulata, appearing rather deeply reticulate than punctate; the punctures not confluent; forming rows on the temples; posterior margin of the head subcarinate; no carina between the antennæ ; posterior ocelli . 31 mm . apart, . 19 mm. from the compound eyes; slightly behind the apex of the latter; these small, .63 mm . long, narrowly oval, somewhat pointed below, their inmer mangins parallel ; the face wide; antenne placed .10 mm . apart, . 29 mm . from the compound eyes, below the midale of the latter; in the female (Fig. 5s') much shorter and thicker than in reticulatu, 24 mm . thick at the thickest part, which is berond the middle; scape one-fouth as long as the flagellum; two-thirds longer than joints three and four together; pedicel equalling the first joint of the flagellum in length; antennæ of the male (Fig. 57) of equal thickness throughout; the seape one-seventh as long as the flagellum, a little shorter than joints three and four together; pedicel as long as the first joint of the flagellum.

Body short, about one-quarter narrower in proportion to its length than in reticulata; length 2.5 mm . ; width 1.3 mm . ; height 1.9 mm . I'ronotum not forming a visible collar, humeral angles very short, the front of the clorsum appearing squarely truncate; mesonotum and seutellum convex, without an sign of lateral, anterior or parapsidal grooves; the whole back appearing as though withont sutures; mesonotum and scutellum punctured similarly to the head; vertical part of the pronotum apparently roughened; its postero-lateral angles also roughened; the upper posterior part of the mesoplenra ocenpied by an oval, moderately polished, oblique depressed area, with a few minute punctulations: the anterior swelling deeply punctate behind, roughened in front; the entire venter coarsely punetured, the scupture largely hidden by the vestiture; propodeum very shallowls reticulate, the retienlations much lengthened and closely parallel on the sides (Fig. 3) : deeper above the petiole. Niddle coxie . 2 m m. apart, .60 mm . from the front, and .48 mm . from the hind coxar; the latter .12 mom. apart; furcula short, indistinct, concealed by the vestiture, not evidently forked.

| mm |  |  |  |  |  |  |  |  |  |  |  |

The tarsal spur is about oue-half the length of the metatarsus, the latter is three-fourths longer than joints $3-4$ together; claw similar to reticulutn, rather smaller; posterior coxg hairy beneath; trochanters mode and polished within. clothed on the onter side with short hairs; femora minntels roughened, elothed with fine hairs; tihie longitudinally aciculate, sparingly hairy, clavate at apex ; tarsi densely covered with fine hairs; tihice and tarsi without spines.

The distance from the metanotum to the petiole is . $4 \times \mathrm{mm}$., the petiole is 1.03 mm. long, the abdomen 1.32 mm . long; petiole obliquely finely and closely striate on the sides and above. Abdomen orbicular, smooth and polished, the secomd segment occupfing three-fourths its length; segments beyoud the third visible only at their extremities. Length 6 mm .

Hub.-Pennsyvania (Philadelphia, July 3, 1899 ; Delaware Co., July 14,1898 ; Lehigh Gap, July 1, 1897 , and July $18,1900, \mathrm{H}$. L. Viereck; August 1903, J. C. Bradley ; Virgimia; Canala; New York (Flatburh, L. I., J. L. Zabriakie. July 2s, 1893; Ithaca, July $17,1904, R$. S. Woglum ; July 9, 1904, July 17, 1905, J. (i. Barlow) ; Michigan (Fold Lelge and Constantine ; Kansas (Lawrence, June 18, 1896, H. Kahl; Bahlwin, June, J. C. Bridwell.

Type.-t, 8 , in the author's collection. Paratypes in the collections of the American Entomological Society; United States National Museum; Cormell U'niversity and Shode Ishand Agricnltural College. The type female shall take precedence over the type male.

The most abundant species of the genus in the north.
S.-Black; anterior and midde legs brown. Clothed with white hairs. Head from above transversequallate; the anterior edge betreen the eyes prominent, not evenly comvex nor emargimate mesally: the space behind the eyes medium. lrofile somewhat pointed above broadest helow the antemma; eres oblique, slightly emarginate externally ; forehead flat; temples moderately narrow above, much widened below; malar space slightly less than one-half the length of the eves. Face from in front nearly round, slightly prolonged below, eyes slightly prominent; no antemmal basin; apex of mandibles red; the checks are separated from the face by distinet arinat, passing from the upper angle of the base of the mandibles to the eyes, then parallel to and but a short distance from the inner margins of the latter to slightly above the insertion of the antennse; face and clrpens mot gibbous; face, forehead, vertex, temples antichorks closely, coarsels and umbilieately punctured; the panctures less distinct aromad the antennar, arranged in rows on the temples; head narrowed behind the eyes; posterior edge not very sharp; no carina between the antenne; Hhe later inserted below the middle of the compound eres, plainly subclateate; sape about one-quarter as long as the thagellum, two-fifths longer than joints $3+4$ : pedicel over three-fiths as lonse as the first joint of the flagellam.

Body short and stout. l'ronotum not forming a visible collar; humeral angles rounded off; mesonotum and scutelhm strongly convex, without parapsidal. lateral or anterior grooves; a straight transverse suture betwern the mesolum and scutellum; vertical part of the pronotnm smooth, polished and impunctate: the polished area on the mesoplenra is irregular, extending two thinds of the way to the coxa, broken by a few confluent pits in the contre: the groove not very deep nor prolonged to the coxa; the anterior swelling full, sparingly punctured with large shallow round punctares, among which are a few minute panetulations; mesorenter similarly punctured; metarenter more coarscly pumetured, but the punctures obscured by the vestiture; two distinct oblique carinæ on the metapleure (Fig. 8), the first prominent and sharp, with a depressed brod fossa bebind it ; the reticulations between the two caringe are form times as long as broad, rather regularly arranged, with a few irregular cross-pieces; behind the second carina the reticulations at the sides are square, the mesal ones elongated, forming a ronghly triangular area ontside of which the reticulations on the propodeum are of moderate size and depth and hexagomal in shape; above the petiole the propodenm is conrsels punctate. Middle coxse far apart, nearer to the hind than to the front pair; furcula with very short rounded lobes.

The tarsal spur is me-half the length of the metatarsus; tibix minutely spined. Wings hyaline.
letiole more or less smoth, polished, with a few punctures, these somewhat dilated and oblique on the sides, a few short oblique ridges at the base of the sides, but not appearing obliquely or longitudinalle grooved or striate. Abdomen orbicular, much less compressed than is usual in the subfamil?, smooth. polished. Length 7.5 mm .

This is the largest species of Hyptio that I have seen. It is about equal in size to a small specimen of Evonia appendigustor.

Hab.-New York (Jthaca, J. H Comstock).
Type.-One female, in the collection of Cornell University.
Hyptiat thoracicat blanchard.

b. $\ddagger$.-Dark red; abdomen, petiole, legs, venter and antennat biack; metapleare amd forehead dark. Sparingly clothed with white hairs. Ihead seen from above transverse, the eyes rather mominent. very little space behind them, the anterior edge hetween them very slightly colvex, the posterior margin slightly coneave, reflexed. Profile irregular, narrow and pointed above, widest below the antemare forehead flat ; eyes oblique; temples narrow above considerably widened below; malar space (.45 mm.) one-third the length of the eye ( 1.44 mm.); cheeks incurved. Face from in front equilaterally triangular, with rounded basal corners; mandibles deeply ponctumed at their base, their lips red, .7! mm. from base to base; palpi dark; clypens separated laterally by a short
impressed suture; cheeks separated from the face by a broad ridge, extending upward close to the inner margin of the eyes; the elypens and face gibbous: face, forehead, vertex, temples and checks rather closely hut shallowly umbilieately punctate, the punctures deepest on the vertex, in rows on the tomples, smaller than in prosetethetra: the antenne filiform in the male, distinetly clavate toward the middle of the flagellum in the female, inserted in a slight depression considerably helow the middle of the eyes; no interantennal carina; scape a little less than one-fifth the length of the flagellum, one-serenth louger than joints $3+4$; pedicel less than one-half as long as the third joint. Alitrunk short and stout. Pronotum straight, truncate, not incurved, nor prolonged at all into a collar; the humeral angles scarcely sharp, not prominent; mesonotum and sentelium distinetly convex; lateral and anterior grouves absent, the parapsidal grooves very fantly impressed; the folished area on the mesopleure not large; a distinct romb pit in the centre, and a larger one at the upper corner; the groose distinct and reaching to the coxit ; the anterior swelling full and impressed with round punctures, a little smaller than those on the dorsum, numerous minute punctulations letween the lower ones; the renter is similarly ponetured, the metarenter a little more coasely: the mesonotum, seutellum and propodenm above the petiole are closely, coarsely and umbilicately pubctured, the punctures quite large; the propodenm below the petiole is reticulate; the sides of the propodenm and the metaplenre are sculptured as in Fig. 6.

Periole smooth and polished, with scattered ill defined punctures. Ahdomen orbicular, smooth and polished. Length 6.5 mm .

A specimen from New Jersey is entirely black and may be distinct.

Mab.-Florida (Jacksonville, Crescent (ity, Piscayne Bay) : Vircrinia; Georgia (Tifton): New Jersey (I) Costa, Joly 19, '()', E. Datceke).

Desrihed specimen in the anthor's collection.
In 1840 Blancharl dercribed Eeranin thorncion and his deseription may apply either to a true Evania, which is highly improbable, because we know no North American species that are real in color, to an Eromiclla or to a Myptio. In $184 t$ Guérin referred to lilanchard's species under the same name without attempt to change its limitation. It has been common among collectors to call all the more or less red species of Myptin necurring in North Americal thoracica, and hence it seems well to determine that henceforth until Blanchard's type be rediscovered the name thoracien Blanchard shall apply to the real species of Hyptia, which I have abowe deseribed mader that name. In 1841 shuckard, evidently matware of Blancharl's work, desoribed H!ptium thoracicum, basing the form Hyptiam on the acrasative meed hy Illiger in his original montion of the genns, are chewhere detaled. By a figure of the wing

Shuckard leaves no doubt as to the generic place of his species, a true Hyptic. The simplest course to adopt in treating it is to establish that henceforth, until Shuckard's type be examined, it is a synonym and likewise a homonym of Blanchard's thorucica, and therefore has no standing. Therefore, when Shuckark's type can be examined, if it proves to be the same as the species that I have described, no further change need be made; if different, it will remain a homonym, though no longer a synonym, and a new name will have to be given it. On the gromen that Blanchard's name thoracica had been previonsly used, Westwood in 1851 proposed the name dorsalis to replace it. But thoracion hal not been previously nset other than in manuscript, hence dorsalis Westwood has no standing whatsoever, except to invalidate as a homonym dorsulis Cameron, proposel for a Central Americim species and replaced by cameroni Schletterer. The name dorsalis has been nsed without shadlow of reason by collectors for Eveniellu semaordu.

Now further confusion arises from Schleterer who indicates the possibility of synonymy as follows: he refers thoracicu Blanchard, thoracica Guérin, and dorsulis Westwood to the Mexican "zteka Schletterer; thoracicu Guérin again to the Asiatic dimidiatu Fabr.; thoracica Shuckard to ocellaria Schletterer from Mexico and the Antilles. In every case except in the reference of thorucica (nuérin to dimidiato he refers them with an interrogation mark; climidiuta and thoracicu Guérin he maker definitely identical, and we would have to consider this as determining the position of the epecies until the type be rediscovered, were it not for the palpable absurdity of identifying it with an Asiatic species without any canse. Identification of thoracica Guérin with dimidiata Fabricius would also necessarily include thoracicu Blanchard and dorsalis Westwood. So we shall have to leave Schletterer ont of consideration in this calse for he is very evidently in error.

1Iyptia floridiana Ashmead.
1901. Hyptia floridena Ashmead, Can. Ent., xxxiii, p. 302.

190: . Brachyqaster floridamus Kieffer, Gen. Insee., ii, 1. 5.
Q.-Dull black. Sparingly elothed with short white hairs. Head seen from above transverse, subquadrate, angles romded, the eyes orcopying almost the entire width; posterior edge tuncate; anterior edge between the eyes convex. not noticeably emarginate mesally. Profile elliptical, somewhat pointed above: eyes oblique; forchead lat; temples quite narow above, three or more times as wide below; malar space (.2: mm.) one-half as long as the eyes (. 48 mm .) :
cheeks considerably incurved. Face from in front romd, the eves not prominent; no antennal basin; mandibles reddish-yellow, roughened, Al mm. fom base to bise; sides of the clypers without : limiting suture; cheeks soparated from the face br a distinct carina. extending from the upper angle of the hase of the mandibles outward to the base of the eres, then inward parallel to and but slighty removed from the inner margins of the eyes to just above the altitude of the insertion of the antenus; elypeus and face not gibbons; face reticulate, the retienlation somewhat transverse; forehead and rertex with regular, not very deep punctures, evenly placed at about their diameter's lenglh apart; tenuples with about two rows of punctures; cheeks with confuent punctures; head rounded behind the eyes, posterior margin not sharp, indintinctly carinate: no carinu between the anteme. Dosterior ocelli . 24 mm . apart, 07 mm , from the compound eres, small: the latter of medium size, rather broadly ovate, widest above, the inner margins parallel, 45 mm . long. Antemme inserted . 0 . mm. apart, . 17 mm . from the componnd eres; the flagellmu somewhat thickened berond its base; scape threc-sixteenths as long as the flagellom, one-fifth longer than joints $3-1$, pedicel four-fifths as long as long as the first joint of the fiat gelium. Alitrunk short, 1.0 s mm. long, . 5 j mm. wirle, 1.01 , mm, high, markedly rapering toward the proporlem. Iropodemm not forming a visible collar, the homeral angles sharp: mesonotnm and scntellum convex, without sign of anterior, lateral or parapsidal grooves, a distinct transerse suture between the mesonotum and the sontellum; entire dorsum punctured like the vertex; a large rhomboidal. highly polished, impunctate area occupies the entire mesopleurat. traversed mesally by an ohligut broad fossa, in front of which it is considerably swollen ; the venter is much narrowed; a suture on the posterior margin of the polished area separates the mesoplenre from the metapleure; the latter sepaad ted from the propodeum hy a distinct carina, behind which is an ohlique depressed smooth polished area, with a few elongated reticulations anteriorly and poateriorls; behind these is a second carina with a smooth area behind it; the metaplenta are coarsely covered below with a few large very shallow round punctures; the propodeum lateralls and posterionly is very shallowls reticulate. Middle coxa about .31 mm . from the front and .12 mm . from the hind coxte.

The tibial spur is one-half the length of the metatarsus; the later is threefifths longer than joints $2 \mathbb{1}$ together; the claw is very small, with a tooth within about as in reticuluta; tibise and tarsi withont spines.

The distance from the metanotum to the point of insertion of the petiole is . 24 mm., the petiole is .53 mm . long, longitudinally carimulate; the ablomen is round, smooth. polished; the second segment large, taking up three-fourths of its entire length: the apical segments are somewhat exposed. Length थ. smm .

This is the smallest specier of Eraniid that I have seen, although sereral recently described species are slightly smaller. It j: quite distinct from all the other species in our fana, and scems more closely related with the Neotropical than the Nearctic species. Dr. A.hmeal erroneonsly states that the typer are males.

今, 乌.-Blaek; anterior tihir testaceons. Head and body clothed with comparatively long white hairs. Head seen from above transverse-quadrate; the space behind the eves medium, not inflated laterally; the posterior angles shightly rounded; the anterior edge between the eyes convex, emarginate mesally. Profile narrowed in front above the eye, widest at the antemæ: eye slightly ohlique; forehead slightly consex, almost flat; temples moderately narrow above, more than twice as wide at the base of the eyes; malar space ( .48 mm .) one-half as long as the eres ( .96 mm .) ; cheeks incurved so that the base of the mandibles is not visible from the profile. Face from in front almost round ; no anteunal basin; mandibles deeply punctured at base, their mesal portion red; .77 mm . from base to base; palpi pale; clypeus produced mesally into a round point, the lateral angles rounded; separated laterally by a short poorls defined suture; the eheeks are separated from the face by a distinct carina extending from the upper angle of the base of the mandibles outward to the base of the eyes, then inward parallel to and but slightly separated from the inner margin of the eje to just above the altitude of the insertion of the antenur ; the middle of the face and the elspens form a gibbous area bounded by the lateral groores of the clypeus; face, forehead, vertex, temples and cheeks coarsely, closels and umbilieately punctured, the punctures rarely confluent, smaller around the base of the antemne, coarsest on the temples and vertex; posterior margin of the head sharp, subearibate; no carinæ between the antennæ ; posterior ocelli .31 mm . apart, .12 mm . from the componand eyes, slightly below the middle of the latter ; antennæ thickened mesally ; seape one-quarter as long as the flagellum, one-half longer than joints $3+4$; perlieel two-fifths as long as the first joint of the flagel1 nm . Alitrnnk short and stont ; length 2.5 mm . ; width 1.9 mm . ; beight 2.2 mm . l'ronotum not forming a visible collar; humeral angles sharp; mesonotum and scutellum strongly convex, without any sign of anterior, lateral, or parapsidal grooves; an indistinct transperse suture between the mesonotum and sellellum; these closels, coarsely and umbilicatels punctured, the punctures not confluent; vertical part of the pronotum impunctate, polished, a few transverse wrinkles on its postero-lateral edges, in front of the tegule ; the upper jart of the mesopleura is a large, highly polished, impuinctored, depressed, rhomboidal area, with a few irregular punctures and grooves in the centre, ending below in an oblique depression, heyond which the mesopleure are distinetly swollen in an oblique direction toward the coxæ, this swelling and the mesoventer sprinkled with a few smaller romnd punctures, between which are a considerable number of minute punctulations; metasenter coarsely, closely and umbilicately pumetate; propodenm shat lowly reticulate, the reticnations lengthened on the side (Fig. \%) : above the petiole the propodeum is coarsely punctate. Middle eoxse .19 mm . apart, . 4 mm. from the frout and .96 mm . from the hind eoxa the latter . 24 mm , apart; furenla short, the prongs eonsisting of mere ronnded knobs.

The tarsal spur is one-haif the length of the metatarsus, the latter is one-third longer than joints: 4 mited; the chaws are of moderate size, slender, inenred,
with a bunt tooth beneath considerably shorter than the apical ray; the posterior cosat are sparingls pitted beneath, less moticeably so above: a ring at the base is smooth and polished; the femora are polished posteriorls; fincly ronghened above; the tibize roughened, rather thickly clothed with silky hairs, among which are a number of minute stonter spines, as also on the tarsi. The wings are hraline, somewhat milky.

The distance from the metanotum to the insertion of the petiole is .i2 mm .. the petiole is 1.44 mm . long: the ahdomen 1.7 mm . f petiole coarsely puncturet above, the ventro-lateral angles ridged, the under surface smooth. Abdomen smooth, polished; the second segment much the large.t. Length 6.5 mm .

Hub.-New Jersey (Clementon, June 25, 18.99, ©, collected and presented to the author by Mr. H. L. Viereck); Ohio ( $\delta$, smdusky, Cedar Point, July 2, 1908).

Hyptia nyctoides n. sp.
(Fig. 4.)
Entirely eoal-black. Clothed with white hairs. Head seen from above distinctly transerse-quadrate, the eses rather prominent; the anterior margin not convex or mesally emarginate. Profile rounded above, eyes high, slightiy oblique; temples broadened below; malar space one-fouth the length of the eye. Face from in from almost round, eyes not prominent, no antemal basin or interantemal carina; extreme apex of mandibles red, the rest black: onls a quite indistinet carina separating the face from the cheeks; face and elypeln scarcely swollen; forehead, vertex, temples and cheeks clonty, not very coarsely, evenly punctured, the punctures in rows on the temples; the face ronghly but rather shallowly reticulate-puncured ; the eompond eres small, the antema insorted below their middle, neat? filiform ; scape one-sixth as long as the flagellum, less than one-fifth longer than joints $3+\mathbf{4}$; pedicel four-tiftheas long as the third joint. Alitronk short and stout; pronotum scarceis prolonged. slightly transversely incurved; humeral angles sharp; mesonotum and scutellum distinctly convex; punctuations on them smooth, close, a bittle coarser than on the forehead; those on the propodem above the petiole close, numerous and smooth. but only about one-half the diameter of those on the dorsum proper; the lateral. anterior and parapsidal grooves wanting ; the whole mesoplenge smooth and highly polished, two or three pits in : hongitudinal row across the centre; the venter with numerous coarser punctures, coarsest on the metaventer; the seulpture of the metaphure and sides of the propodem at shown in Fig. 4 : the propodeum postemiorly and helow the petiole shallowly, not very coarsely reticulate.

The tibial spur is one-half the lengtb of the metatarsus; the latter is one-fifin longer than joints $2-5$ togetber; the tibise are minutely spinulose. The wings are hyaline.

The petiole is closely, moderately correly punctured. The abdomen is orbicular and polished. Length 5.5 mm .

> Hab.--New Jersey (Farmingtale, Juty $1 \pm, 1899$, H. L. Viereck). Type.-In the author's collection (one specimen).

## IIyptian prosetethetran sp.

(Fig. 1.)
Black, except the prothorax, mesonotum, seutellum and most of the mesopleure red. Clothed with white hairs. Head seen from above transverso-quad. rate; the anterior edge slightl? emarginate: posterior corners rounded; the efes slightly prominent. Profile rounded above; eyes oblique; temples narrow above, considerahly broader below; malar space less than one-third the length of the ere. Face from in front ovate, almost round, more pointed below; eyes not prominent; no antennal basin or interantennal carina ; apex of mandibles red, their base black; the cheeks are separated from the face onls by an indistinct cama, extending but a sbort distance along the margin of the eye; face and clypens not swollen; face, furehead. rertex, temples and cheeks closely, eorarsely and umbilicately punctured, the punctures coarser and more distinet than in $H$. hyptiogastris: eren and smooth on the forehead, rertex and temples, rough on the face; arranged in two or three rows on the temples; the antennæ inserted below the middle of the eompound eyes; filiform; seape a little less than onefifth as long as the flagellum; one-fifth longer than joints $3+4$; pedicel threefifths as long as the third joint. Alitruuk short and stont. Pronotum slightly prolonged into a collar, thansversely incurved mesalls; bumeral angles rather sharp; mesonotum and scutellum strongly convex; lateral and anterior grooves abseut; the parapsidal grooves absent, except for a slight impression near the anterior margin; the polished area on the mesopleura is large, with two small pits on the posterior part and oue larger one above; the groove is long and deep, extending to the coxæ; the anterior swelling full, with a few quite small punctures; the mesoventer also with small punctnres; the metarenter more coarsely punctured; the mesonotum and scutellum closels, coarsely and umbilicately punctured, the punctures large, smaller on the propodeum above the petiole, reticulate below the petiole. The sculpture of the metapleura and sides of the propodeum is as shown iu Fig. 1; furcula with only very short lobes.
The tibize are minutely spinnlose. The wings are hyaline.
The petiole is punctured on the side, a very narrow smooth stripe above. The abdonen is orbicular and polished. Length 6.5 mm .

Hab.--Tifton, Georgia.
Type.-In the U. S. National Muserm. A specimen without locality in the collection of the American Entomological Society.

# Hyptia hyptiogastris n. sp. 

(Fig. 2.)
Black; the face below the antenna, the dorsum and the upper part of the pleure red; front legs brown. Clothed with white hairs. Head seen from above strongly transverse; the anterior margin neither noticeably prominent nor mesally emarginate. l'rofile rather broad, romded above; eyes nearly straight; forehead flat; temples not much widened brlow; malar space not one-half the length of the eyes. Face from in front oval, a little pointed below ; eyes slighty prominent; wo antemal basin; apex of mandibles red, their base black; the cheeks are separated from the face by an indistinct carina, passing from the upper angle of the hase of the mandibles to the eyes, then within and close to
their inner margin to the altitude of the antemae; face and clrpeus somewhat swollen into a tubercle in the middle; face, forehead, vertex, temples and cheek, closely, coarsely and umbilicately panctured, the punctures more even and smooth on the forehead, vertex and temples, arranged in rows on the latter; no caring between the antenme; these inserted below the middle of the compound eyes; filiform; scape a little under one-fifth as long as the flagellom; a little under one-sixth longer than joints $3+4$; pedicel three-fifths as long as the third joint. Alitrunk short and stout, tapering posteriorl. ; pronotum not forming a distinct collar; humeral angles rather sharp; mesmotum and scutellum somewhat conrex; with indistinct parapsidal and no anterior or lateral grooves; vertical part of the pronotum smooth, polished, impunctate; the polished area on the mesoplenre large, shading below into a punctured area; the groove for the reception of the legs rather deep and prolonged; the anterior swelling and the entire venter and the cosx are thickly covered with large, sometimes contluent punctures, among which are numerous minute shallow punctulations; the sculpture of the mesupleure and forward part of the propodenm is as shown in Fig. 2 ; entire dorsum to the petiole coarsels evenly punctured, propodeum below the petiole shallowly reticulate; middle coxie moderately far apart; furcula consisting of two short tubercles.

The tihice are minutely spinulose. The wings are hyaline.
Petiole smooth and polished on the very top, obliquels wrinkled and striate on the sides. Abdomen orbicular, smooth, polished. Length 6.5 mm .

Mab.-Georgia (Tifton).
Type.-In the United States National Inseum.

## Hyptiat dexitian m. sp.

(Fig. 5.)
Q.-Black; the four anterior legs beyond the coxze testaceous. Head and entire dorsum closels, coarsely, umbilicately punctured, the face less coarsely and more shallowly. Antennæ filiform, the scape a little over one-fifth longer than joints $3+4$; pedicel four-fifteenths the length of the scape, ofer ome-balf the length of joint 3 ; joints 3 and 4 equal. Humeral angles rather sharp: mesopleuræ smooth and polished, the anterior swelling punctured; lateral area of the propudeum consisting of three rows of oblong interstices (Fig. 2-). l'osterior tibial spur one-third the length of the metatarsus; the latter longer than the remaining joints together; claw with a small tooth within. l'etiole obliquely coarsels wrinkled, above lese distinctly wrinkly-punctate.

Hyptiat brevicalcat Kieffer.
1904. Iyptia brevicalcar Kieffer, Ark. f. Zool., i, p. 541.

* J. L. 6 mm . Schwarz. Mandibeln bramn. Gesicht schwach behaart, und sowie die stirne und der Scheitel netzartig punktiert; letztere whbehart: Schläfen nach unten erweitert, mit einigen schr groben Längsrunzeln, dazaw ischen grob punktiert; Wangen halb solang wie der sehaft, grob punktiert, vom Gesicht durch eine tiefe und breite sich am inneren Augenrande noch fortsetzende Furche getrenut; zwei sehr feine maeh ausen bogig gek riummte Furchen reichen von den Antemmen bis zum Munde und begrenzen einen elliptiselien
gewölhten Raum; Stirne fast flach, kaum eingedrüekt. Fühler dnnkelbraun, kaum vor der Angenmitte inseriert; vor ihnen keine wallartige Erhebung; sehaft so lang wie die 3 folgendeu Glieder mitsammen ; 2. Glied die Hälfte des 3. wenig überragend ; dieses fast doppelt so lang als dick, nur wenig länger als das 4. Thorax oberseits mit groben, sieh berübrenden und benabelten Punkten; Tegulse gelb; Parapsidenfurchen fehlend; Propleuren gerunzelt ; Mesopleuren in der oberen hinteren Häfte glänzend glatt, vorne und mnten grob punktiert; Metaplenren und hinterer senkrecht abfallender Teil des Metanotums grob netzartig gerunzelt; Metastermalfortsatz kurz, bngegabelt, nur ausgerandet. Flügel glashell; Medialader vorhanden; Hinterfïgel mit einer Subrostalader und 4 Frenalhäckehen. Beine dunkelbraun, die vorderen rotbrann; bintere Hüften punktiert und behaart, von den mittlereu um ihre ganze Länge entfernt; ${ }^{\circ} \mathfrak{l}$ й gerer Sporn der hinteren Tibien nur ein Drittel des metatarsus erreichend; dieser solang wie die 4 folgenden Glieder mitsammen. Abdomenstiel rotbraun. walzenrund. doppelt so lang wie sein Abstand vom Vorderrande des Metanotums, oberseits glatt, mit einigen Puktem, seitlich sehräg gefurcht. Wiseonsin."

I am muable to determine the relation of this species to our other American species from the above description, and have omitted it from the key.

## THE ENOTIC EVANIIN E.

## TABLE TO THE GENERA OF EV゙ANIINE.

1. Abdomen of the female distinctly triaugular, the apex produced into a short process from which issues the ovipositor (Fig. 1s) ; abdomen of the male more or less narrowly oval; antennæ inserted in a single distinetly impressed basin, bordered usually at least on the lower side by a carina; usually an interantennal carina present; metauotum as seen from the side more or less deeply depressed, the sides of the depression abrupt (Fig. 62), (Tribe Evaninni)
(2).

Abdomen of the female nearly eireular (rarely somewhat triangular), the apex not produced into a process (or rarely slightly produced); abdomen of the male the same shape as that of the female (sometimes oval in Evaniella); antenna not inserted in a distinct impressed basin, at least without any earina below or beside them, rarely if ever between them, the front usualls distinctly convex; metanotum as seen from the side less deeply depressed, the sides sloping gradually (Fig. 63), (Tribe Hyptini) . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . (す).
2 . Front wings with the cell $R-1$ st $R_{1}$ and $M_{4}$ not coalescent, $M_{3}++$ and $r-m$ usually wot interstitial, but strongly arcuate (Figs. 75-79)
[Cells $R+1$ st $\mathrm{R}_{1}$ and $\mathrm{M}_{4}$ coaleseent; $\mathrm{M}_{3} \vdash_{4}$ and $r$-m interstitial, forming a nearly straight line (Fig. 82) . . . . . . . . . . . . Evanisens Szepligeti.* ${ }^{*}$ ]
8. Posterior tibise and tarsi provided with very distinct stout spines, arranged rather regularly over their surface. . . . . . . . . . . . . . . . . . . . . . . . . . . (4).
Posterior tibise and tarsi without any spines (Fig. 60) ; labinm modified into a highly chitinized pear-slaped plate, which nearly covers and conceals the ligula (Figs. $2 x$ and 29) ................. Wiviniat Fibricius.

I have not seen this genus, but believe that it belongs in the 11 pptini rather than here.
4. Labium modified into a bighly chitiuized pear-shaped plate. which nearly covers and conceals the ligula. Hab.-Hawaii.

Szepligetellatn. ren.
Labium consisting of a much narrower less chitinized oval plate, longitudinally divided in the middle; the lignia much longer and not concealed (Fig. 26). Hab.-Austro-Malayan and Australian subregions

5. Forewings with only one or two completely enclosed cells......................... Forewings with six or seven completely closed cells ....... .............. 6 .
6. Forewings with sevell completely closed cells, the base of the free part of M arising from the radius near the stigma (Fig. 83).

Evaniellan Pradley.
Forewings with only six completely closed cells (Figs. 81 and 82), or if with seven, then the base of the free part of Marising from the radins far before the stigma (Fig. 80 ) ................................................ (T).
7. Base of the free part of $M$ between $m-c u$ and $R$ wanting, or indistinct and arising from $R$ far anterior to the stigma (Figs, 80 and 81

Zenxevania Kieffer.
Base of the free part of M present between m-cu and $R$, wating between mcu and $r-n$, so that cells $R+1$ st $R_{1}$ and $M$ are coalesced (Fig. 8\%).

Evauiserus Szepligeti.
8. Forewings with only the cells C and 3 present and distinctly closed (Figs. E4 and 85)
(9)

Forewings with only cell ( 1 present and closed (Figs. S6 and 5 ) ..........(10).
9. Flagellum of the female suddenly clavate from about the middle (Fig. 55) ; mesopleure with a distinctly polished impunctate area; claws with the inner ray much larger and stunter than the outer ray (Fig. $\overline{5} 1$ ).

Semaeomyia 11 gen.
Flagellum of the female evenly thickened from base to apex; mesopleurawithout anspolished impunctate area; claws with the onter ras much the larger and more prominent (Fig. 53 ).

Senisodogaster Bradley ( $=$ linuchyguster mreoc.)
10. Cubitus present in the front wings (Fig. E6) ; hind legs always much shorter than in any other genus of the subfamily that I have seen (Fig. 61).

Hyplia Hlliger.
Cubitus absent, so that there are onls two reins present in the front wings,
C and $\mathrm{Sc}+\mathrm{K}+\mathrm{M}$ (Fig. st................ Vinniellns Enderlein.

## EVANIA Fabr.

## Type.-Evaniu appendigaster Linn.

For the description of this genus see the first part of this paper There are 6.3 species of which 35 come from the Neotropical rearion. The species of the Patearctic region are well tabmlated by Szepligreti.* He includes chinensis, however, in his Oriental region.
E. uppendigaster will not be inchaded in any of the tables except

Annales Musei Nationalis Hnngarici, i, p. 379. 1903.
the following, although it has become naturalized in every region. The student should become familiar with it before using any of the other keys. Probably the majority of the Nentropical species really belong to Evaniella.

## TABLE TO THE SPECIES OF EVANIA OF THE PALEARCTIC REGION.

1. European and Mediterranean snbregions . . ...................................... . . (2).
Manchurian snbregion . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . (9).
2. Face and cheeks longitudinally and obliquely striate ...........................(6).
Face and cheeks not striate, but wrinkled, punctate or smootl.............. (3).
3. Scutellum flat, undivided............................................ . . . . . . . . . . (4).
Scutellum convex, emarginate and therefore two lobed; face and mesonotum punctured; forebead depressed. $\dagger . . . . .$. ....schlettereri Kohl.
4. Forehead excavated....... ........................................................... (5).
Forehead fiat; face and mesonotum smootb, polished, with a few very fine scattered punctures. Black...................appendigaster Linn.
5. Face with distinct scattered punctures; mesonotum with nomerous sharp punctures. The petiole and more or less of the thorax red.
dinnidiatia Spinola
Face withont distinct punetures. Thorax and abdomen black.
comalis Kieffer.
6. Antenne inserted equidistant from the anterior margin and the middle of the eyes
Antennre inserted near the middle of the eyes . . . . . . . . llablollata Kieffer.
7. Head, at least the face, white tomentose ; front excavated; temples wrinkled and pnnctate. . ................................................................ . (8).
Head smooth and polished; front covvex, except for a small depression hehind the antenna, traversed by a longitudinal carina; temples smooth. slriaticeps Kietler.
8. Hind wings with eleven frenal hooks; face, vertex and cheeks nearly smooth; propodeum and pleuræ weakly tomentose.........pinctitin Brulle. Hind wings with eight frenal hooks; face, vertex and cheeks as thickly tomentose as the forehead. . ................................incertal Kieffer. 9. Face finely and thickly punctured .............................inensis Szepligeti.

Evaniat dimidiata Spinola.
Szepligeti has properly credited this species to Spinola. The reference of it in Schletterer and in Dalle 'Torre's "Catalogus Hymenopterormm" to Fabricius, Syst. Piez., p. 179, 1804, is a pure mistake. Fabricius does mot mention the name, and Spinola describes it as a new species.

TABLE TO THE SlPECIES OF EVANIA OF THE ETHIOHIAN RECION゙.

1. Wings brown . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . (2).

Abdomen reddish-yellow. Length 8 mn.......................................... (9).
9. Face strongly striate; ocelli as far from each other as from the compound eyes; petiole wrinkled. Color black...pinbipeninis Szepligeti, Lombok.
Face finely striate; ocelli farther from the compound eyes than from each other; petiole scarcely wrinkled. Color yellowish-red.
dullelir: Szepligeti, Lombok.
10. Habitat, Java . .11.
Habitat, Singapore or the Phillipines. Length 4.5 mm , or less. Posterior tibiæ with a yellow or white ring; first three to five joints of the antennæ red; forehead punctured or with a finely striate area on each side and a smooth space between . . . . . . . . . . . . . . . . . . . . . . . . . . . . . (13).
11. Dorsum reticulate; length 6 mm ; forehead strongly striate or with tiro striæ on each side and one in the middle, the rest interrupted by a smooth spot above each antenna. Entirely black, except the four anterior tibiæ and tarsi are brown, joints 2,3 and sometimes 4 are yel-lowish-white, and the base of the posterior tibiæ may be white...(12).
Dorsum rather coarsely and thickly punctured; length 4.5 mm . forehead smooth and polished, except for five carinæ. Rust-red, except the head above, antennæ beyond the fonrth joint, posterior legs except the coxæ, trochanters and base of the tibiæ are black; the face and cbeeks. apical half of the petiole and the abdomen are dark brown; antennal joints 2-4, hase of the posterior tibice and basal half of the petiole yel-lowish-white.
minlticolor Kietfer, Java.
12. Forehead with two strong carinæ on each side close to the eye, and another in the middle, the rest interrupted below the middle by a smooth area above each antenna. Base of the posterior tibiæ not ringed with white ; antennal joints 2, 3 and 4 dirty yellowish in the female.
enderleini n. spl., Java.
Forehead, face and cheeks finely striate, the middle carina more prominent than the otbers. Tibire at base and joints 2 and 3 of the antemma white..........................................ninalatai Taschenberg, Java,
13. Forehead coarsely punctured; length 4.5 mm . Broad hand at the base of the hind tibie, and the tibial spurs yellowish-white; first five segments of the antenna honey-yellow.
anninlipes Ashmead, Phillipines.
Forehead on both sides finely striated, in the midde a fine kecl, and the space between smooth; length 2.2 mm . Ring at base of the hind tibize and the first three antennal segments only, yellowish-red.
szepligedii n. nom. (= parva Szepligeti, nom. preoc.), Singapore.
14. Face and forehead thickly pubescent, apparently withont senlpture. Head, antennat and legs yellowish-red.

1
loninolfiensis Szepligeti, Lombok.

Face weakly swollen. smooth and polished, in the middle a small tubercle. Yellowish-red; the head, antemae, hind legs, abdomen and petiole. except the apes, black; first two and half of the third joint of the flagellum, apex of the petiole. trochanters and base of the tibice white: anterior and middle legs except the coxa and trochanters brownish.

Kriegeriana Enderlein, West Bomeo.
Nvania suepligetiin, nom.
1903. Exumia para Szepligeti, Ann. Mus. Nat. Hungetrici, vol. i, page 381, is prencoupied by Evania purva Enderlein, Archiv. fïr Nature., 1901, p. 193.

## Evallial enderleinin. sp.

## Fig. 59, 65 and 78.)

§, ㅇ.- Entirely black, except the form anterior tibix and tari are brown, and segments 2,3 and 4 of the antenme of the 9 are dirty yellowish-white. Head seen from above transverse; eves vers promicent and with but little space behind them, the ncciput being almost wanting: posterior ocelli equally far fromeach other and from the compound exes. Profile with the compond eyes projecting above the vertex and very small, scarcely extending below the level of the antennee, so that the malar space is about equal to the length of the eyes. The clypus and face are very convex : abont six carine on each side of the face converging towards the apex of the clspeus, and ahout double their own length apart; a more strongly marked carina in the centre; abont five caringe on the cheeks extending from the base of the eses to the mandibles; the temples above the base of the eyes and the vertex behind the ocelli are coarsely subreticulate. The forehead has a strong mesal carina, and two cariue on each side paralle] to the inner margin of the eyes, the remaining carine are intermpted below the neelli bs a depressed smonth area above each antenna; this area, while appearing smonth, is really slightly shagreened. In the male the sculpture of the head is much obscured by a dense whitish vestiture, which is present on the bead, thorax and propodeum minch more strongly than in the female, giving a decided silvery sheen; in the female the scape is very long (Fig. 59), a little less than one-half as long as the flagellum ; at the end of the sape the antenat are strongly elbowed. and the flagellum is thickened and strongly recurved at joints 57 ; joint 3 is about the length of joints $4+5$, which are about equal in length to each other. and of the flagellum onls the first joint is twice as long as broad; in the male the antenme are not elbow or recurved, entirely filiform, much longer than in the female; the scape about the length of joints $2+3$; the latter about the length of joint 4 or 5 . which are subequal, and all the joints of the flagellum are at least twice as long as broad.

Entire thoras and propodenm very coarsely reticulate. except the upper fart of the mesopleure are smooth and polished, and the entire venter is more shatlowis and less coarsely reticulate; the humeral angles are square; mesonotal grooves lacking; the furcula has divergent but hlunt and not vers long tynes (Fig. (6).

Tlie wings are hyaline (Fig. ©) ; the veins M beyond $\mathrm{m} \cdot \mathrm{cu}, \mathrm{M}_{1}+2, \mathrm{~m}$ and the longitudinal part of $\mathrm{M}_{2}$ are very faint. The posterior coste, femora and thise are coarsely punctured and hairy; the tarsal claw is very pecnliar, in that it is hifid and the inner ray much stronger and longer than the outer ray, and thrown
somewhat out of plane with it; both are strongly incurved; the clas of the male is smaller; the longer tibial spur is a little less than one-half as long as the metatarsus, this is as long as the remaining joints together ; a few minute spines on the tibiæ, difficult of detection.

Petiole on the sides obliquely coarsely wrinkled ; above coarsely punctured ; a little longer than the distance from its hase to the metanotum. Abdomen of the female subtriangular, the prgidium produced into a point in which the osipositor is concealed.

Hab.-Java, 3 males, 3 females.
Type.-Male and female in the collection of Cornell University.
The type female shall take precedence over the type male as type of the species.

## TABLE TO THE SPECIES OF EVANIA OF THE NEOTROPICAL REGION.

1. Argentinian and Brazilean subregions.............................................. (2).

Central American subregion . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . (29)
2. Antenne filiform or gradually thickened.................... . . . . . . . . . . (3).

Antennæ incrassate beyond the fifth joint; head and thorax reticulate-rugose. Black; mesonotum and legs red. Length 7 mm .

Daraensis Spinola, Brazil.
3. Furcula with more or less distinct tynes. . . . . . . . . . . . . . . . . . . . . . . . . . . . (4).

Furcula truncate, without distinct trnes; head smooth, very finely striate in front; dorsum smooth, polished. Red; scape and femora darker; abdomen brownish-red. Length 6 mm .
rufit Taschenberg, Argentine Republic.
4. Furcula with divergent tynes. . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . (5).

Furcula with parallel tynes. . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . (11).
5. Petiole smooth and polished . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . (6).

Petiole rugose or striate . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . (7).
6. Forehead wrinkled; face very finely punctured ; chceks entirely smooth; rertex with shallow punctures. Black; face and cheeks yellow; the upper half of the thorax red; antennæ beneath and the four anterior legs yellowish-red; base of the posterior trochanters white. Length

Forehead in the middle and above the antenne finely rugulose, toward the antennæ and the eyes subcoarsely punctured; a distinct median carina; face longitudinally carinulate, shining, toward the anteung finely longitudinally striate; cheeks polished with very fine punctures; vertex moderately densely punctate. Black; middle of the antennæ and the legs more or less white. Length 7.5 mm .
siguata schletterer, Colombia.
7. Face not striate. (8).

Face with a few indistinct strice; two arcuate carina running from the base of the antenne to the mandibles; cheeks and temples smooth, polished, with a few scattered punctures; forebead with scattered rather coarse punctures, among which fine punctures are thickly set; mesonotum polished, with thickly set microscopic punctures; petiole coarsely. rugosely punctured. Length 7 mm......brevigena Kiefler, Brazil.
-. Face finely punctured ; cheeks and forehead sometimes wrinkled ..... 9
Ifead coarsels punctured. Ferruginons; head, antemme.abdomen and poste-for legs back, otber legs brown. Length 10.5 mm .
molbilis Westwomd, Brazil. 9. Nesonotum not rugose ; petiole one and one-half times as long as the distance from its origin to the scutellam . . . . . . . . . . . . . . . . . . . . . . . (10)
Mesonotnm rugose or rigose-punctured ..... 9a).
IM. Mesonotnm weakly shiming, thickly and finety rugose-punctured, also withlarge irregular shallow punctures; face weakly swollen, pulished, veryfinelr, shathowly and thickly pmoctured; forchead and vertex thicklybut rather finels and deeply ragose-punctured. Yellowinh-red; apexof the antemme, abdomen and hind legs, except the coxa, back.
Mesonotum strongly rugose; petiole twice as long as the distance from its origin to the scutellum; head with thick but not deep punctures: cheeks with a few punctures. Black; the head and antennee except the last forr segments and the apex of the minth orange-yellow ; tarsi of all legs and tibixe of the forelegs brown. Length 6 mm.
hatuschi Enderlein, Ecuadur.
10. Cheeks. forehead and vertex wrinkledi ; mesonotum with punctures confluent mesally : petiole one and one-half times as long as the distance of its orign from the scutellum. Yellowish-red; the abdomen and apex of the antenne black ; posterior tibiæ and tarsi brown. Length os man.
pulelnerimat Szepligeti, Brazil.
IIead smooth and polished; forelnad and vertex not wrinkled, but very finely functured; face with microscopic scattered punctures; shoulders strongly right angled; mesonotum smooth, polished, with whly minute punctures; petiole finely longitudinally striate. Length 4.5 mm. . . . . . . . . . . . . . . . . . . . . . . . . . lonngilniهis Kjeffer, brazil
11. Propodeum with a smonth polished area around the petiole . . . . . . . . . . . 12. Propodeum reticulate around the petiole, except sometimes above it . . . (13). 12. Entire head and dorsum smooth and polished; petiole rugosels punctured. Length 5 mm.......................politan Schletterer. Sonth America.
Face smooth and polished in front, longitudinalls wrinkled toward the eres and antennae; rest of the head punctured to rogose-punctured : mesonotum with moderately large, mesally dense punctures; petiole smouth and polished. Length 5 mm............areolatia Schletterer, Brazil.
13. Tibial spur two-thirds as long as the metatarsus or nearly so...... .... 14.
Tibial spur not over one-half as long as the metatarsus . . . . . . . . . . . . . . . . . . 0 .
14. Petiole smooth or punctured... ............................................. (15)

Parapsidal grooves obsolete : fac mesotboras red; antennal. ole white. Length $6.5 \mathrm{~mm} . .$. .
36).
nunctured. Black: pronotum and rochanters and apex of the petianterala Cameron, Panama.
36. Longer tibial spur one-half as lovg as the metatarsus or less. . . . . . . . . . . (37).

Longer tibial spur three-fourths as long as the metatarsns; face pmotured. not keeled mesally. Black; face white. Length 5 mm .
alloispina Cameron, Panama.
3i. Hind coxa obseurely or finels putetured. . . . . . . . . . . . . . . . . . . . . . . . . . (3s).
Hind cosz coarsil? to rugosely punctured. . . . . . . . . . . . . . . . . . . . . . . . (39).
35. Forehead with a mesal keel, on each side of which it in shagreeved; mesonotum rugosely punctured. Black; antemal joints 24 and apex of the petiole white, Length fommornaticormis Cameron, Panama. Forehead without a mesal keel, finely punctured, a depression above each antema; middle of the mesonotum with large punctures, sides shining. aciculated. Thoras, head, seape and feet in part red; antemal joints $2-4$, trochanters and apex of the petiole white; abdomen black. Length 6.5 mm

Variscornis Cameron, I'anama.
39. Mesonotum mesally with large deep punctures. laterally slighty shagromed; scutellum rugosely punctured. Black. Jength f mm.
rumifionns Cameron, Panama,
Mesomotum mesally suhcoarsely and sparingly, anterionly very finely, punctate, laterally smooth ; sentellam coarsely and rather closely punctate; posterior coxa rugosepunctate above. Black: thoras foluginous. Length 6 mm. . . . . . . . . . . . roblefatichletterer. Mexico.

## 

Type.-Evania sericea Cameron.
This genus differs from Acanthinevania in the month parts, which resemble more closely those of Eraniar the labrum is broad amd highly chitinized and the ligula long ; the third joint of the labial palpus is very much inflated, two or three times as broad as long. The posterior tibix and tarsi are spiny, as in Acanthinevania.

So far only one species is known, the only member of the sulnfamily mative to the Hawaiian Istands.

I take great pleasure in dedicating this genus to Herr Victor Szepligeti, whose work on the Evaniidse as well as on other insectis most admirable.

## Sueplisetella sericeal Cameron.

Three males, Kona, Hawaii, September, 1896 (Koebele); July, 1842, 600 feet (Perkins). One female, Kona, Hawaii, July, 1892. 600 feet (Perkins).

Specimens in the collection of the U. S. National Musemu.

## ACAN'IIINTVANMA n. gen.

Type.-Evania princeps Westwood.
This genus differs from Evanio in the arangements of the monthparts and in the spiny character of the posterior tibie. The labium consists of two moderately chitinized plates which folit in the middle and do not conceal the long lignla ; the third joint of the labial palpi is not dilated and thas not noticeably different from the second (Fig. 26). The cheeks are usually long, and the head seen from in front has usually an oblong appearance. The spiny character of the posterior legs may be used as a reliable recognition character.

The genus replaces Evaniu in the Australian region. The two mingle in the Malayan mbregion of the Oriental, and two African speries are doubtfully referred to this gemus.

> TABLE TO THE SPECIES OF ACANTHINEVANIA. oriental Region, Malayan Subregion.

[^4] Furcula rudimentary ; propodeum wrinkled above; mesonotum with micro-
scopic muctures....................nicholitzi Enderlein, Sumatra.

## Australian Region, Austro Malayan and Australian Subregions.

1. Head and mesonotum distinctly punctured, wrinkled or striate (finely punctured and weakly shining in custraliensis).
Head and mesonotum smooth and polished, the latter with a few scattered punctures. Tibia, tarsi and apex of the femora of the anterior legs and antennal joints $4-7$ rustr 5ellow. Length 9 mm.
arogenteocandit Enderlein, New Guinea.
$\because$. Furcula with parallel trnes . ...................

Face finely punctured, with a long median carina. Length 7 mm .
Incida Schletterer, Australia.
5. Length 1114 mm ; face channcled or finely striate . . . . . . . . . . . . . . . (6)
length 4 mm . ; face finely wrinkled, weakls shining.
anstrallensis Szeplegeti, New Sonth Wales,
15. Face coarsely longitudinally ehanmeled. without a distinct median carina. Length 13-14 mm........................................................ . . 7 ).
Face finely longitudinally striate, with a short median carina. Length 11-1: mm. . . . . . . . . . . . . . . . . . . . . . . . . . . ecinain Schletterer, Austalia.
7. Forehead longitudinalls wrinkled, above, together with the vertex, irregnlarls wrinkled; temples with very coarse punctures, almost reticulate; sides of the face and forehead and the temples strongly silvery hairy.

Drinedp, Westwod., New South Wales and near New Guinea. Forehead and vertex as strongly and regularly channeled as the face; temples longitudinally striate, with coarse punctures between; inner orbit and the temples weakly hary....striatifions kieffer, Australia.
S. Truncature of the propodeum concave, with a more or less distinct mesal angle.
Truncature of the propodeum that or convex very slighty impressed in simi-lis and similate(15)
9. Truncature of the propodeum moderately impressed, the surface coarsely reticulate
. (10).
Truncature of the propodeum very deeply impressed, the middle entirely smooth; mesonotum coarsely and sparingly pinctured.
impressat Schletterer, Philippines, Polynesia and New Guinea.
10. Face with a few longitudinal wrinkles, a distinct mesal rarina, and sometimes one on each side, in addition to the carina separating the face from the cheeks; mesonotum coarsely and rather thickly punctured. . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . (12).
Face punctured or rogosely punctured, without mesal, but sometimes with lateral carinæ; petiole one and one-half times as long as the distance from its insertion to the scutellum or less. . . . . . . . . . . . . . . . . . . (11).
11. Face plainly but shallowly wrinkly punctured; mesonotum with coarse punctures, mesally dense. Black.
medianat Schletterer, New Britain.
Face finely punctured with a few coarse punctures; mesomotum polished with very fine scattered punctures and a few coarser ones. Black; scape, femora and tibiæ of the four anterior legs yellowish-red..
tomentos: Szepligeti, New Guinea, New Pommern.
12. Face with three carinr, one in the middle and one on each side separating the face from the cheeks; posterior metatarsus as long as the three following joints together. . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . (13).
Face with five carinæ ; one in the middle aud two on each side, the outer pair separating the face from the cheeks; posterior metatarsus onlo as long as the two following joints together; petiole with scattered punctures, twice as long as the distance from its origin to the scutellum. Black; forelegs, except the coxse and trochanters, middle femora and tibir. hind coxæ and under side of the femora, propodemm and petiole, red ; tarsi of the middle legs, trochanters, upper side of the femora, and the tibiat and tarsi of the bind legs reddish-brown.
quinquelineata Kieffer, Anstralia.
13. Petiole with scattered punctures; one and one-half times as long as the distance from its origin to the scutellum ... ............................. (14).
Petiole thickly punctured among longitudinal wrinkles; twice as long as the distance from its origin to the scutellam. Entirely black, except a red spot at the base of the hind femora..villosicirns Kieffer, Australia.
14. Red; base of the cheeks, a stripe on the face, antemme, middle and posterior tarsi, bind tibia, end of the middle tibia and of the hind femora and the abdomen black or brownish-black.
versicolor Kieffer, Australia
Black; front tibise and tarsi, and the abdomen, except its apex, red ; middle and hind legs dark reddish-brown.
versicolor var. eryiluogaster Kieffer, Australia.
15. Propodeum above the petiole more or less rugose; face rugose or striate ; parapsidal lines inconspicuous or obsolete . . . . . . . . . . . . . . . . . . . . (16).
l'ropodeum above the petiole not rugose. . . . . . . . . . . . . . . . . . . . . . . . . . (18).
16. Petiole longitudinally wrinkled or striate; the longer tibial spur as long as or longer than one-half the metatarsis. . . . . . . . . . . . . . . . . . . . . . . . (15).

Petiole subdensely confluently punctured; fonger tibial spur less than onehalf the length of the metatarsus: face shallowly searry punctured: forehead vers thiekly and corarsely punctured ; mesomotum coarely. in the middle densels, punctured. Black. Length 12 mm .
humerata schletterer, Australia.
17. Face shallowly pmetured and indistinctly longitudinally wrinkled; mesonotum scarry punctured, forming iudistinct wrinkles posteriorls : petiole rather coarsels longitudinally wrinkled. Black; antennar and legs brown. Length f mm......helleri Schletterer. East Australia.
Face coarsely, longitudinally to obliquely striate; mesonotum indistinctly longitndinalls wrinkled, with thick, eoarse, searrs punctures among the wrinkles; petiole obliquely to longitudimally striate. Black. Length 9 mm ...................... scabra Schletterer, Australia.
15. Petiole obliquely striate above..................................................... (19).
letiole not striate but smontb, punctured or at most rugose-punctured ahove......................... .... .................................... (22).
19. Mesonotum coarsels rugosely punctured ; parapsidal grooves absent . . . (20).

Mesonotum sparingls coarsels punctured; farapsidal grooves very indistinct; humeral angles very sharp. Length 7 mm .
angulata Schletterer, Anstralia
2i). Posterior ocelli farther from each other than from the compond eyes. . (21).
['osterior ocelli nearer to each other than to the compound eres........(24).
21. Head and mesonotum coarsely rugose ; posterior legs plainls wrinkled on the sides; longer tibial spur somewhat longer than one-half the metatarsus. Length $7 \mathrm{~mm} . . . .$. .... major Szepligeti, New sonth Wales.
Vertex punctured; forehead wrinkled; face longitudinally striate, the strize sometimes confluent ; mesonotum coarsels rugosely punctured ; posterior legs smooth or mieroscopieally pnoctate, a very few larger junetures on the femora, aud the cose cuarsely punctured.
sxepligeti n. sp., New South Wales.
2:2. Petiole smooth abore (ご3).
Fetiole punctured or rugosels punctured above (25).

23 . Fosterior ocelli nearer to each other than to the compound eyes; beal and mesonotum rugose. Length $\overline{\mathrm{y}} \mathrm{mm} . . .$. ............................. (24).
Posterior ocelli a little nearer the compond eyes than to each other: face longitudinally to irregularly wrinkled; mesonotum rugose-puntate. Length - 9 mm. . .nnullerii Achletterer, Anstralia and New Britain.
2f. Salpe of the male somewhat longer than the third joint, this twiee an long as the second and shorter than the fourth.
similis Szepligeti, New Sonth Wales.
Scape of the male somewhat shorter than the third joint ; sape of the female as long as joiuts $2+3$; the thirl joint three times as long as the second and somewhat longer than the fourth.
similantal szepligeti, New south Wales.
25. Face punctured....................................................................

Face ruguse, at least laterally, or striatt ........................................ (2t).
26. Longer hind tibial spur shorter than one-half the metatarsus; furcula obture. with scareely distinct tynes see 16 ). Length 12 mm .
hmmerata schletterer, Australial

Longer hind thbial spur as long as one-half the metatarsus; furcula with distinct trnes; petiole finely punctured; face sparingly scarry puncpunctured ; mesonotum very thickls and coarsels punctured. Length

27. Petiole twice as long as the distance from its origin to the metanotum ; mesonotum only slightly convex . . . (28).
Petiole only one and one-half times as long as the distance from its origin to the metanotum; mesonotum and scotellum strongly consex; rather closely and very coarsely scarry punetate, with a tendency to wrinkling; petiole distinctly and rather closely punctured. Length 79

28. Petiole more or less rugosely punctate, lateralls obliquels rugose; mesomotum in the middle coarsely and thickly punctured, at the sides almust smooth. Black, except the tibiæ and tarsi of the forelegs and the antennæ except the apex are reddish-yellow. Length 6 mm .
erythrocnemis Schletterer, New Britain.
Petiole finely and densely pnoctured; face longitudinally wrinkled; forehead rugosely punctured; mesonotum subcoarsely and moderately densely punctured. Black. Length $10-11 \mathrm{~mm}$.

Iongigenan Schletterer, Australia.
Aennthinevanian princeps Westwood.
(Figs. 10, 48, 64 and 79.)
One male and five females in the collection of the American Museum of Natural History, and one female in the author's collection, all from New South Wales.

## Acanshinevania genalis Schletterer.

(Fig. 26.)
One male and three females in the collection of the American Museum of Natural History, and one female in the author's collection, all from New South W'ales. The propodeum is rufous.

Acanthinevania longigenas schletterer.
Mrele.-Scape about as long as joint three; pedicel about one-fourth as long as joint three; this scarcely shorter than the fourth joint: abdomen oval. Entirely black. Length 8.5 mm .

One male in the collection of the American Museum of Natural History.

# Acanthimevanian szepligeti n. sp. 

(Fig. 47.)
Female-Black. Sternum sericeous. Head seen from above transverse-quadrate; the eyes prominent; the vertex behind them deep. Eyes moderately long and narrow ; their inner margins divergent below ; the malar space long, twothirds or more of their length; the antennte inserted a little above the base of the eyes; temples broad, very broad below; posterior ocelli a little nearer the compound eyes than to each other; vertex umbilicately punctured, the punctures
well separated; forehead depressed, coarsels punctured to longitudinally wrinkled ; a strong mesal carina and two lateral carine on the convex face which remain parallel, not converging toward the apex of the clypens; the lateral carine join anterionly the strong carima which separates the cheeks from the face; between the carine the face is longitudinally striate, the strixe nol coarse; the cheeks below the eves are longitudinally wrinkled; the temples are punctured like the vertex; the scape is slightly longer than the distance on the vertex between the compound eres; abont one-tenth longer than joints $2+3$; the pedicel is a little under one-quarter the length of the third joint, which is onequarter longer than the fourth.
The humeral angles are very short, the anterior margin of the dorsum appearing as a straight line; the pronotm and upper corver of the mesoplenre are smooth and polished; the mesonotum and scutellum arc coarsely, rugosels punctured, tending to longitudinal wrinkiing; the propodeum and less markedly the pleurae are reticulatels punctured; the venter more finely scarry pouctured; the furcula has parallel trnes.
Posterior cosa ciosely, coarsely punctured; rest of the legs vers finels punctured with a few larger pook marks on the femora; posterior tibise and tarsi with strong spines; the longer tibial spur considerably longer than one-half the metatarsus: the latter as long as joints $2-4$ together ; claw (Fig. 47) with a small tooth within, at right angles to and much smaller than the outer ray. Wings lyaline; reins M beyond $\mathrm{m}-\mathrm{cu}, \mathrm{M}_{1}+2, \mathrm{M}_{1}$, longitudinal part of $\mathrm{M}_{2}$ and m faintly marked.
Petiole coarsels obliquely wrinkled, above longitudinally. Abdomen black. polisher, subtriangular; the second to fourth segments with a few punctures above: prgidium prodnced into a short process which normalls conceals the ovipositor.

Inbb.-New South Wales.
Type.-One female in the collection of Comell University.
I take pleasure in dedicating this species to Herr Victor szepligeti, who has made substantial contributions to our knowledge and classification of the Evaniidat of this and other regions.

EVANIELLA Bradley.
Type.-Evamiella vemuoda Bradley.
For a description of this gentus see page 142.
It is probable that nearly all the neotronical species listed under Evamict really belong here. I have made no attempt to separate them.

The following new species is included in the table of the genns: Evania, in which the determination of all specimens falling in this genus from outside of the United states shoukd he sought.

Here belongs Eirania semiruoru Cresson from Cuba.

## Evaniellat camenoni n. sp.

Black; pronotum and mesonotum red; anterior legs, exfept the apex of the trochanters externalls, which are brown, and base of the middle and posterior trochanters, yellow. Sparingly pubescent. Head from above transverse-quadrate; eyes prominent; posterior ofelli nearer the compound eyes than to each other. From the side the temples are narrow, little widened below; the eyes very large; the malar space quite small. From in front the face is nearly round, the inner margins of the compound eyes almost straight, slightly diverging helow; the sculpture of the face almost obscured by vestiture, in a favorable light seen to be finely and irregularly but not very roughly punctate; a long distinct carina extends on each side from the outer margin of the clypens upward to below a point midway between the antenng and the margin of the eyes: forebead with fine elose punctures, in front of the compound eyes these are replaced by larger more separated round punctures, which continue on the vertex, temples and cheeks; forehead with a distinct median earina. Antenna filiform; scape over four times as long as the pedicel. five-eighths as long as joints $3+4$; the pedicel one-third as long as joint 3. the latter three-fourths as long as joint 4.

Pronotum scarcely notehed ahove by the mesonotum; humeral angles squarely cut; mesonotum anteriorly and the side of the scutellum with a few scattered round punctures, otherwise smooth; anterior, parapsidal and lateral grooves very distinct; mesopleure punctured, with a small smooth and polished area above; furcula with short indistinct parallel trnes; propodeum reticulate; the reticulations produced into oblique bars over a short area on the sides. Posterior tibial spur two-thirds as long as the metatarsus.

Petiole impunctate; abdomen broadly elliptical ; the apical segments pubescent.
Hub.-British Guiana, Bartica, May 10, 1901, R. J. Crew.
Type.-In the author's collection.

## ZEUXEVANIAKieffer.

1502. Zenxevania Kieffer, Gen. Insec., 2, p. 4.

## Type.-Evania dinarica Schletterer.

In this grenus (see Figs. 80 and 81 ) the cell $\mathrm{M}_{4}$ is elongate and situated nearer to the base of the wing than in Evania, the veins m-cu and part of the hase of $M$ form its anterior bomblary, and join together to form a regular arc. At the same time $r$-m and $\mathrm{M}_{3}$ 4 hecome interstitial, appearing as a single ahmost longitudinal vein, instead of r-m joining Ma short distance before the separation of $\mathrm{M}_{\mathrm{I}_{2}}$ and $\mathrm{M}_{3}$ 4, as is the case in Eeanio. It is evident that the modification has proceded from the type that we have in Eremia by the hase of the free part of M migrating back ward ahong F to a distanee almost halfway between the base of the wing and the sitima, and then in some of the specice becoming lost, hat in a new epecies that I have here to describe momaning as a faint vein (Fig. 80).* The mouthparts are shown in Fig. 32.

Ocems in the lalearetice, Ehhopian and Oriental regions. Six speries in all.

* This has been recently described as Paremuia, see addenda.

## TABLE TO THE SIECIES OF ZEUXEVANIA.

1. Palearctic region . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . ${ }^{(2)}$ ).

Ethiopian region. . . . . . . . . . . . . . . . . . . . ....... ............. . . ...................3).
Malayan subregion of the Oriental. . . ................. ........................ t).

Petiole striated. . . . . . . . . . . . . . . . . . . dininirica Schletterer, Austria. Egypt.
3. Petiole twice as long as the distance of its insertion from the metanotum, smooth and impunetured.
teunisiylns Enderlein, German East Africa.
Petiole but little longer than the distance of its insertion from the metanotum, smootls and with a few punctures.
globiceps Enderlein, (ierman East Africa.
4. Entirely black; petiole obliquely striate........javialiuat Westwood. Jawa.

Prothorax and mesothorax, anterior part of the metapleure and anterior coxa red; petiole smooth and polished.......schiletrereri u. sp., Java.

## Zuncevinial seliletiereri n . sp.

(Figs. 32, 50. 50.
Q.-Black, except the prothorax and mesothorax, anterior part of the metapleure and the anterior cosre are red; the anterior tibiæ and less distinctly the middle tibise are rellowish-brown; base of the fosterior tibia and trochauters white. Slightly sericeous. Head seen from above subglohular; posterior margin truncate: deep behind the eyes, which are not prominent; the postero-lateral corners slightly ronnded. The profile is broad, the eye moderately long. only slightly oblique; the temples only slightls widened below; the antenna inserted on the convex forehead at about the lower third of the eye; malar space ahout one-third the leugth of the eye or less. Face from in front almost round. Entire head very minutely rather closels punctate, appearing smooth under a low power; a earina separating the cheeks and face: two short tooth-like proresses just below the antennæ; ocelli forming an equilateral triangle ; the posterior ones about equalls far from each other and from the compound eyes; antemat filiform, the scape little longer than joint three, the latter subequal to joint four, and more than twice as long as the pedicel.

The humeral angles rouuded; the mesonotum, mesoventer and scutellum punctured siailarly to the head: the upper part of the mesopleuræ vaiously finely punctured, wrinkled or smooth; the rest of the propodeum shalbows reticulate; the furcula with divergent trues, but these are very small and at first glauce one would be led to think it trancate and withont tynes; the middle and posterior coxæ are placed close together.

The wings are hraline, a little dusky at the apex (Fig. wi). The legs are moderately elongate; the posterior cost elosely punctured ; the tibia and tarsi withont distanet spines; the longer tibial spur two-thirds as long as the metatarsus; the latter as long as joints $2-4$ together; the claw bifid, with a stont inner ray aud a much more slender outer ray (Fig. 50 ).

Petiole smooth and polished; abdomen nearly round, the pygidium not produced.

One paratype hats the apex of the petiole white.
I take pleasure in dedicating this species to Dr. August schlett-
erer, who has done more to bring order ont of chas in this family than any other man.

Hub.-Java.
Type and two paratypes in the collection of the Comell University. One paratype in the author's collection.

EVANISCUS Szepligeti.
(1903. Psendevaniu Kieffer, misprint for Zerxevania, Zeitschr. f. Hym. n. Dipt., iii, p. 111, see corrigenda to volume.)
1903. Evaniscus Szepligeti, Aun. Mus. Nat. Hung., i, pp. 375, 378.

Type.-Evaniscus tibialis Szepligeti.
In the Zeit. f. Hymen. u. Dipt., iii, p. 111, Kieffer says that Evanio trochanterata Cameron and E. marginata Cameron belong to Psendevania (misprint for Zenxevania, see Zeitsch. f. Hym. u. Dipt., vol. iii corrigenla). E. trochanterata Cameron is a true Evania, to which genus it must be returned forthwith. The wing veuation as figured by Cameron in the Biologia Centrali-Americana is that of Evania, and not of Zeurevaniu or other genus. E. marginata is neither an Evomia nor a Keurevaniu, but is congeneric with the subsequently described Evamiscus tibiulis of Szepligeti. Hence it should stand in the genus Evaniscus Szepligeti of which tibiulis is the type.

## TABLE TO THE SPECIES OF EVANISCUS.

1. Propodeum coarsely reticulate

Propodeum rugosely punctured; furcula with parallel tynes.
manginatit Cameron, Guatemala.
2. Petiole curved, with six rather distinct longitndinal cariure, between these strongly aciculated; furcula with divergent tynes.
tibialis szepligeti, Venezuela.
Petiole moderately slender, finely and thickly punctured, on the sides somewhat aciculate...........rifithorix Enderlein, Bolivia and Peru.

## SEMAEMVIIA n. gen.

Evania and Irrechygaster of anthors in part.
Type.-Semcomyia kiefferin. sp.
Color usually black, with more or less red or yellow. Head large, broader than the thorax, scarcely or somewhat transverse as seen from above (Fig. 15) ; eyes large, often very large, extending far toward each other on the vertex and leaving but a small malar space and a narow front (F゙ig. 14) ; ocelli nearly in an equilateral triangle, large and usually very close to the eyes. Antenne filiform in the males, in the females strongly incrassate beyond the fifth serment (Fig. 55). The mouth parts are shown in Figs. 3 : and it.

Body sometimes elongate, the middle coxie being placed far posterionly; mesopleure smooth and polished, with a distinct femoral groove; sculpture of a small area on the side of the propordeum of distinctive character, sometimes smooth and polished; furcula usually consisting of a long process with very small parallel or divergent tynes.

Po-terior legs long; the tarsal claw hifid, the inner ray larger and stouter than the outer one, the latter sometimes nearly obsolete (Figs. 51 and 52).

Wings hyaline; the venation as shown in Fig. 85.
Abdomen similar in both sexes, nearly romnd, the pygidium not produced.

The size is usually small, the thorax slender and tapering posteteriorly. The punctation is generally fine or absent. There are 1.3 species, all from the Neotropical region.

## TABLE TO THE SPECIES OF SEMEOMYIA.

1. Central American subregion . .......................................................... (2).

Brazilian and Argentine subregions.................................................. 3 .
2. Mesonotum plainly punctate; posterior metatarsus plainly longer than the remaining joints taken together; cheeks of the male as long as the seape; first joint of the flagellum of the male one and one-half times as long as the pedicel, second twice as long as the pedicel; parapsidal grooves obsolete; head coarsely punctured; pronotum with prominent humeral angles. Length $3.5-4 \mathrm{~mm} . .$. azteka schletterer, Mexico. Mesonotum smooth and polished, or with a few seareels noticeahle shallow punetures; the posterior metatarsus only as long as the remaning joints together; forehead moderately closely pmotate; temples of even width from above to below; scape of the male one-half as long as joints 2 and 3 ; joint 3 two and one-half times as long as the pedicel ; pronotum with rounded humeml angles. black. Length 4 mm .
nitidit Cameron, Panama.
?. Mesonotum plainly punctured
(4).

Mesonotum not punctured. . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . (o).

1. Propodeum between the metanotum and the insertion of the petiole punetured, not wrinkled; furcula with short divergent trnes.......... (T.
l'ropodeum above indistinetly transversely wrinkled; furcula with parallel tynes. . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . (6).
I'ropodeum retienlate . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . (5).
2. Propodeum on the sides coarsely reticulate; laead thickls and moderately finely punctured; face thickly, very finely and moderately shallowly punctured; mesonotum shiny, polished, the middle pieee with sparee shallow punctures; parapsidal and lateral earine distinct. Length

Propodenm very finely reticnlate, more finely near the lateral edges: head thickls and finely punctured; mesonotnm polished and shins, the middle piece sparsely and finely punctured, the lateral pieces rather thickly and very finely punctured; parapsidat and lateral carinæ distinct. Length $4-5 \mathrm{~mm} . . . . . . . .$. . . . reticulifer Enderlein, Peru.
6. Face finely and densels punctured. Lblack. Length 6-7 mm.
srealleri Schletterer. Brazil.
Face moderately, finely and sparsely pnnctured, with minute intemmediate punctures. Black, except the face, mandihles and anteunæ beneath are pale yellow; the four anterior legs rusty yellow.

Hinvescens Schletterer, Brazil.
7. Face very finely and moderately closely punctate, temples much more shatlowly punctate; anterior part of the side of the propodenm eoncare, with closely parallel cross-bars; body normal, the middle coxa not placed exceptionally distant from the anterior. Red; the face, four anterior legs, posterior coxæ beneath and trochanters at base yellow; abdomen black; posterior legs brown. Length 4 mm .
taschenbergin. sp., British Guiana.
Face less finely aud more deeply punctured; cheeks and temples smonth and polished with a very few minute punctures; anterior part of the side of the propodeum scarcely concave, smooth and polished; without cross-bars, except along the edge. Red; abdomen brown. Length

8. Furcula with parallel tynes. . ...................................................... (9).

Furcula with divergent tynes... ........................... .... ................ (10).
9. (See also fraterna noder 14.)

Posterior metatarsus shorter than the four remaining joints together; longer tibial spur shorter than one-half the length of the metatarsus. Black: first fonr antennal joints and the coxæ except their apex rellowishred; fifth antennal joint and the apex of the petiole white. Length

Posterior metatarsus as long as the remaining four joints together; tibial spur as long as one-half the matatarsus. Fermginons; face, cheeks, temples and two anterior legs white; petiole pale reddish posteriorly, propodeum darkened, especially posteriorly. Length 4 mm .
albatat Schletterer, Colombia.
10. Face distinctly punctured .(11).
Face smooth and impunctate; mesonotnm smooth and polished with fine parapsidal lines. Ferruginons; propodeum black ; abdomen and posterior legs brown. Length $3-3.5 \mathrm{~mm}$.
gayi Spinola, Colombia amd Argentine subregion.
11. Face in the middle with a distinct tubercle; head and face very finely and shallowly punctured. . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . (12).
Face without a median tubercle; head and face less finely punctured...(13).
12. Cheeks smooth, polished and impunctate; antemaze inserted far below the middle of the eyes; ocelli large and close together; humeral angles ronnded; posterior coxa finely punctate; posterior tibial spur one-half the length of the metatarsus. Black, excent the first five antennal joints, anterior legs except the tarsi, middle legs except the tibix and
tarsi, posterior coxæ and thochanters, mesonleurat, venter, spot on the trincature of the propodenm and the anex of the petiole rellow.

('heeks moderately finely and densely punctate; antennae insertad at the middle of the eyes; posterior ocelli a little farther from earh other than from the compound eyes; humeral angles moderately sharp: posterior coxæ beneath sulncoarsels and denseiry pmotured: tibial spur one lialf as long as the metatarsus. Black; four anterior legs brown. Length $3-3 . \bar{j} \mathrm{~mm} .$. İvinaeulan Spinola, Colombia, Clilı.
13. Forehead with a mmber of widely separited fine punctures; face with close fine punctures, transverst wrinkis just below the antennæ. Brown. with antennæ, at least their bases, pale rellowish; anterior and mid. dle legs, posterior femora and tha apex of the petiole whitish. Length
 Forehead and face conspicuously, finely and subdensely punctate....... 14
14. Petiole with only a few shallow punctures. Length 3.5 mm .
friterinal Enderlein, I'eru.
Petiole laterally furmow its entire length.
Doswalis Schletterer, Colombia.

## Senmeonnyia kiefferin. sp.

(Figs. 14, 15 and 52. )
C.-Black; the first fire joints of the antemax, the mesopleure, vertex, large spot on truncature of the propodeum, anteriox legs except tarsi and apex of tibixe, posterior coxa and base of trochanters and the apex of the petiole fellow. Head seen from above (Fig. 15) rounded, somewhat tramsverse, the eyes rery large, on the vertex comparatively close, reaching almost to the posterior margin of the head; ocelli in an equilateral triangle, the posterior ones over twice as far from each other as fron the compound eses. From the profile (Fig. 14) nothing is seen except the componnd eye and a marrow bit of cheek and temple below: the antenma are inserted below the lower two-thinds of the eses. From in front the head is round, the front marrow, the inmer margins of the eres diverging a little below; a distinct tubercle in the middle of the face bebow; face and forebead denselr, finely punctured; ebeeks, temples, vertex and oceiput impmoctate, smooth and polished; scape one-third longer than joints $2+3$; these subequal, as is also 4 ; besond the fourth joint the antennce are strongly inflated, tapering again apically.

The humeral antrles are ronnded; mesonotmm and scutellum and most of the mesoplemre smooth, polished and impmotate; metaplenre and propodenm - ballowly retioulate, the area on the side irregularly sballowly wrindied; furcula with the tynes divergent but very short.

Wings hyaline ; longer tibial sumr one-lalf the length of the metatarsns; the latter one-fifth longer than joints $2 \quad 5$ together ; the tarsal claw small, infid. the inner ras much stonter than the onter one (Fig. 52).

The petiole is smooth; the abdomen ronnt and polished. Length $3 . \bar{\circ}$ mm.
 J. Crew, and presented to the writer by Mr. I Ienry L. Viereck.
'Yype-In the author's collection.

## Nenseomyial baricensis in. sp

(Figs. 33, 34, 51, 55 and 85.)
Q.-Red; apex of the petiole and the four anterior legs rellowish; posterior tarsi brown ; abdomen and antenmæ beyond the fifth segment black. Head seen from above transverse, rounded in front and truneate behind; the eyes very large, reaching far up on the vertex and to the posterior margin; ocelli large, in an equilateral triangle, the posterior ones about their diameter's length apart, a little less removed from the compound eyes. In profile little is visible except the compound eyes; the malar space moderately long, the temples obsolete above, widened below ; the antennæ are inserted below the midde of the eres. From in front the head is slightly triangular, the margins of the eyes diverging below; the face has no median tuberele, is moderately closely punctate; the forehead more closely; the temples and cheeks smooth and polished with onls a few small punctores; antenne shown in Fig. 55.

Humeral angles rounded; the mesonotum smooth and polished, with several moderate sized punctures seattered over it, these a little thicker on the seutellum and on the propodenm above the petiole; anterior, parapsidal and lateral grooves distinct; mesopleuræ impunctate, shining, exeept the anterior swelling which is finels punctured; propodeum except above the petiole shallowly reticulated, the area on the side smooth and shining; the middle coxæ are placed far posteriorly, in juxtaposition to the posterior, the body being considerably elongated; the furenla has very short divergent tynes.

The wings are hyaline. The longer tibial spur is more than one-half the length of the metatarsus; the latter is about one-fourth longer than the remaining joints united. The tarsal claws are very small and mostly broken off in the type, but in the remaining one the inner ras seems to be stout and the outer ras rudimentary (Fig. 51).

The petiole is sparingly punctured above and at the base of the sides, the apex of the sides being transersely wrinkled; it is more than twice as long as the distance from its insertion to the metanotum. Abdomen round, polished. Length 6 mm .

Hab.-Bartica, British Guiana, collected by R. J. Crew and presented to the author by Mr. H. L. Viereck.

Type.-One $\rho$ in the author's collection.

## Semamonyia taselnenbergi n. sp.

Red; face, cheeks and temples, seape beneath, trochanters at base and tibial spurs and apex of petiole yellow; rest of posterior legs and base of the petiole brown; abdomen and propodeum around the coxa black. Head seen from above truncate behind, rounded in front, the anterior edge prominent and emarginate mesally between the eyes; these raching to the posterior edge; ocelli farther from each other than from the compound eres. Profile broad, the temples linear above and widened below; malar space moderate; antenne inserted below the middle of the eyes. From in front the eyes are prominent ; their inner margins diverging below ; face moderately, finely punctured ; temples and cheeks much more sparingly; forehead more closely and coarsely punctured, the vertex smooth.

The humeral angles are rounded; the anterior, lateral and parapsidal grooves well marked; the mesonotum, scutellum and propodeum above the petiole smooth and polished, with few moderate sized scaltered punctures; the mesopleurex smooth and shining; the anterior swelling peppered with exceedingly minute punctulations; the metapleure and propodenm reticulate, the area between them concave, with transverse cross-bars; the furcula has very short divergent tynes.

Wings dusky at the apex. Longer tibial spro one-half as long as the metatarsus; this as long as the remaining joints togetber; claws small, bifid, the inner ray longer and stronger than the outer.
letiole sparingly punctnred. Abdomen round. Length 4 mm .
I take pleasure in dedicating this species to Professor E. Taschenberg, one of the few contributors in recent years to our knowledge of this family.

Hub.-Bartica, British Guiana, collected by R. J. Crew, May 17, 1901.

Type. - In the author's collection.
SEMIEODOGANTER n. Hom.
(Figs. 30, 31, 53 and -4.)
Brachygaster Stephens, preoc., Syst. Cat. Brit. Insec., 1, p. 343.
The name Brachyguster has usually been dated from Leach, 1817, Edinburgh Encyclopaedia, but the name as there employed is a nomen mudum and without standing. At the place cited, in an article on entomology', Leach under the genus Evania mentions Evania minutus. As synonymous with this, he parenthetically mentions Irrachygaster minutus Leach MSS. That is Leach's only reference to the mame in print. The first person to properly use the name in Hymenopterat was Stephens in 1829. But in 1826 Meigen had used it in Diptera, and it has since been used in Crustacea and Coleoptera. So it is necessary to change it.

The only described species is the European minutu Ol., which Kieffer* maintains is different from the minuta of Schletterer.

HyPTIA Illiger.
Type.-Evania petiolata Fabricius.
The species petiolata of Fabricins is mecognizable, and until its identity be ascertaned, Evania thoracica Blanchard, as identified in the first part of this paper, shall stand as type of the gemms.

For description of the genus, see the first part of this paper. It is confined to the Nearctic and Neotropical regions.

Pronotum mesally emarginate above ; petiole very sparingly panctured or the sculpture ohscured hr thick white vestiture................... . . 19 .
19. A distinct patch of white hairs near the hase of the abomen above; cheres very sparingls, face coarsely and closely punctured. Black; the funand mesonotum and mesopleura above red. Length 5 mm .
weithi Ashmead, Haiti.
No patch of hairs on abdomen : petiole with a few small seattered punctures. cheeks with a few round punctures; face with an indistinct medan longitodinal protuberance, with larger irregular punctures orer and between which are close minute pmonctures. giving it a roughened appearance; forehead with remarkahly evenly phated, separated. round punctures. Red; antenme, legs, except coxs more or less, vertex and abdomen with petiole hback....... . poeyi Guśrin, ('uba,
20. Face immediately in front of the base of the antennee with a median longitudinal protuberance and vers fine wrinkly punctation: forehead clothed with yellowish hairs: fureula truncate. not forked; the longer tibial spur two-thirds as long as the metatarsus. Rusty red; head in part and the abdomen black. Length 4 mm .
-tinulatar Shlitterer, ('uba.

Face without a protuberance, and coarsely sculptured like the rest of the head; forehead bare; furcula with distinct but parallel tynes; the longer tibial spur scareely one-half the length of the metatarsus. Black; thorax rusty reddish.
bcellaria Schletterer, Mexico, St. Thomas, Cuba.

## Hypilat solor Sehletterer.

This species was described from both North and South America. But such a range seems almost imposible in view of what we know of the distribution of these insects. I believe that two species have been confused, and I have not included it in the North American fauna.

## Hyptia poeyi Guérin.

§.-Red; antenne, vertex, legs, except anterior pair in front whieh are brown, and posterior coxe behind which are red, abdomen wilh petiole, except the apex which is black, yellow. Head from ahove transverse oval, the anterior margin prominent; the vertex forming a rather sharp crest upon which are placed the ocelli; the posterior oeelli more than twice as far from each other as from the compound eyes. From the side the forehead eonvex; the eye moderate; the temples moderate, slightly widened below; the malar space about onethird the length of the eye. From in front the head is nearly round, somewhat pointed below ; the inner margins of the eyes almost parallel; an ill-defined carina separates the cheeks from the face and runs within and removed from the eyes to the altitude of the base of the antennæ; face with irregular eonfluent coarse punctures, which are every where covered and ahmost obliterated by minnte punetures; foreliead covered with vestiture, among which a number of round remarkably evenly placed punctures are visible; temples and cheeks with a few moderate punctures. Antenne filiform; the pedicel one-third as long as the seape, two-thirds as long as joint 3 ; the latter equalling joint 4 ; joints $3+4$ equalling the scape.

Pronotum emarginate above; humeral angles moderately sharp; mesonotum and scntellum evenly eovered with round, moderate, separated punctures, between whieh are a few small ones; parapsidal grooves indistinetly marked in front; mesopleure smooth and polished, mueh depressed mesally ; venter minutely punctulate; propodenm shallowly reticulate, coarsely punctured above between the scotellnm and the petiole; the sides with two oblique carinæ, between whieh are almost obliterated irregular cross-bars; furcula with short parallel indistinct tryes.

Posterior tibial spur four-fifths the length of the metatarsus; the latter almost as loug as joints 2-5 together; claws with the imer ray much stonter than the outer.

Petiole with a few small seattered punctures; abdomen highls polished; the remaining segments almost concealed under the second and thind.
Q.-The fenale differs from the mate in having vers donse sellow pubesence on the forehead, giving it a very striking apporance of bearing a yellow mane; the erest on which the ocelli are placed is not so prominent ; the flagellum is distinctly thickened beyond its second joint, tapering aqain at the apex ; the pedicel two-minthe as long as the seape, two-thirds as hong as joint 3 ; the latter one-half
longer than joint $4 ; 3+4$ over one-half the length of the scape. The tibial spur is almost as long as the metatarsus; the second segment occupies almost the entire abdomen.

I have reeognized this species from two prohably anthentic specimens sent to Mr. Cresson many years ago and now in the collection of the American Entomological Society. As the origimal description is too meagre to identify the species from, I have drawn up the above description from two specimens sent me by Professor C. F. Baker, collected by him in Havana, Cuba.

## Hypliat lbakeri n. sp.

Brownish-black ; scape and pedicel, four anterior legs mostly, and base of posterior trochanters yellowish. Ocelli almost twice as far from each other as from the compound eyes; latter large; temples narrow, widened below; malar space small; face with a prominent medial V-shaped area, roughened with minute and coarse punctures, on the sides two rows of large separated punctures; a row of punctures surrouuds the eyes, and border the temples and cheeks posteriorly ; the latter otherwise very scantils punctured; antenne slightly thickened, the scape equalling joints $2+3+4$, over three times as long as the pedicel, which is one-fifth less than joint 3 ; the latter slightly less than joint 4 ; the forehead, vertex and entire dorsum are regularly covered with round separated hut rather close punctures, the humeral angles sharp; the mesonotal grooves wanting; mesopheuræ smooth, polished ; propodeum shallowly but very coarsely reticulate laterally and posteriorly; furcula short, with parahlel tynes. Posterior tibial spur one-half the length of the metatarsus, which equals the rest of the tarsus. Petiole lougitudinally striate. Length 2 mm .

Hub. -Champerico, Guatemala, C. F. Baker, one specimen.
Type.-In the collection of C. F. Baker, Para, Brazil.
IIyptia johnsoni Ashmead.
The locality for this should be Jamaica and not Philadelphia, as I pointel out in the Canadian Entomologist, xxxvii, p. 64 . Besides the type in the U. S. National Museum, there are two specimens in the collection of the Americam Entomological Society.

EVINELIJIN Enderlein.
1905, April 11th. Evaniellus Enderlein, Zool. Anzeig., xxviii, p. 70.
Type.-Evaniellus permuns Enderlein.
Evidently unaware that I had established a genus Evaniellu for Seania culifornica Ashmead and others in February, 1905, in the Canadian Entomologist, Enderlein in April of the same year cetab)lished L'voniellus for some South American species. It is to be regretted that the two names are so near alike in form, but the recommendation under Article 36 of the International Code as
given by Dr. Stiles provides that names are not to be rejecterl becanse they differ only in termination, so we must retain both names, confusing as such a course may seem in the present instance.

Evaniellus seems to differ from Hyptia only in the loss of Cu, so that it is one step further in the evolutional series that the family presents in the reduction of the wing veins (Fig. 87).

There are four species, all from the Brazilian region of the Neotropical.

## TABLE TO THE SPECIES OF EVAN゙IELLUS.

1. Face finely punctured. . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . (2).

Face rugose or ruguse punctured.
2. Head above rather coarsely punctured; face fimels and thickly punctured ; diamerer of the hind ocellus less than its distance from the compound eyes; petiole strongly. thickls and coarsely punctured, on the side distinctly aciculate. Length $3 \mathrm{~mm} . .$. bervanus Enderlein, Peru.
Head above rather finely and thickly punctured; face very finely and shallowly pnnctured; diameter of the hind ocellus equal to its distance from the compound eyes; petiole long, finely but sharply longitndinally striate. Length $4 \mathrm{~mm} . . . . .$. .............aeilis Enderlein, Peru.
3. Head rather coarsels ringose; thorax cuarsely rugose-punctured, the parapsidal lines not very distinet, the lateral parts polished behind; propodenm coarsely reticulate; petiole distinctiy longitudinal wrinkled. Black; flagellnm rust red; wings light brown. Length 5 mm .
brasiliensis Szepligeti, Brazil.
Head above rather coarsely punctured, face very finely wrinkly punctured; mesonotum coarsely punctured parapsidal furrows marked by a thickly punctured line; propodenm above thickis punctured, on the sides more reticubate; petiole rather strongly, very thickly punctured and longitudinally striate. Black; the face, cheeks, temples, scape and anterior pair of legs rust rellow; the middle legs rellowishbrown. Length about $\& \mathrm{~mm}$.
chalcialipenmis Enderlem, Butivia.

## ADI)ENDA.

The descriptions of the following species were not accessable to the author until too late for inclusion in the keys.

## EVANIA.

Oriental Region.-E. hirtipes Kiefter; peradenige C'am.; interstitialis Cam. ; hirsutu Enderl.; hirwutu var. rujofemoruta Enderl.: setosa Enderl.; binghami Can.: deescrnsis Cam.

Ethiopian Region.-E. schönlandi Cam. (allied to Veurevumiu); meridionalis Cam.; fulvospinu Cam.; peringueyi Cam.; rimosit Enderl.

Neotropical.-E suncti-puuli K ieff.

## ACANTIINEVANIA.

Oriental.-A. sutunus Enterl.; simillima Endert.
Australian.-A. meratuliensis Cam.

## GEUMEVINA.

 see note below.

## SEMEOMYIA.

Brazilian Subregion.-S. lüderuraldi Enderl.; luctis Enderl.
The author has mot hat access to descriptions of the following species: Evaniu corulis Kieff; tubellutu Kieff.; rujonotatu Kieft.; parculu Kieff; tomentella Kieft.; cunuliculatu Kieff.; bicarinuta Kieff.; carinigera Kieff.; beauforti C'mm. 'The last is probably an Acunthineramia, and said to be close to A. moraukensis Cam.

PAREVANIA Kieffer.
(Fig. s0.)
1906. Parevania Kieffer, Berl. Ent. Zeitschr., li, p. 270.

Type.-Parevaniu semirufa Kieffer.
Kieffer erects this genus for $P$. semirufiun. sp., which is either identical or very close to my Zenserumiu schlettereri described on page 179. About the only difference evident between this genus: and the type of Zencovana-Z. dimurica Schletterer-is that the hase of the free part of MI is not entirely atrophied. For the present, at least, I shonld not incline to assign it more than subgeneric rank.

Enania rubru Cam, is a closely related, although distinet species. Cameron hesitates to place it in Zenuerouiu, with which he admitits affinities, on account of its possessing the longitudinal sector of the base of the free part of M, which he states is absent in Voror"umiut, doubtless thinking of his $E$. marginata, which, however. really belong: to Evaniscus and not Zeurecomia.

## F(ENIN.

I have recently recognized an additional genns of Feninie, resembling Pseudofomus in wing venation, but occurving in California with one new species and in Guatemala. The description of this genns and species and of a new species of forme from C'alifomia, with additional ohservations on the clar-ification of the subfamily, I shall shortly publish elsewhere.

[^6]JUNE. 1908
